2300 Yonge St., Suite 709, Toronto, Canada M4P 1E4

HEARING ON THE PROPOSAL BY THE MINISTRY OF NATURAL  
RESOURCES FOR A CLASS ENVIRONMENTAL ASSESSMENT FOR  
TIMBER MANAGEMENT ON CROWN LANDS IN ONTARIO

IN THE MATTER of the Environmental  
Assessment Act, R.S.O. 1980, c.140;

- and -

IN THE MATTER of the Class Environmental  
Assessment for Timber Management on Crown  
Lands in Ontario;

- and -

IN THE MATTER OF a Notice by the  
Honourable Jim Bradley, Minister of the  
Environment, requiring the Environmental  
Assessment Board to hold a hearing with  
respect to the Class Environmental  
Assessment (NO. NR-AA-30) of an undertaking  
by the Ministry of Natural Resources for  
the activity of Timber Management on Crown  
Lands in Ontario.

-----  
Hearing held at the offices of the Ontario  
Highway Transport Board, Britannica Building,  
151 Bloor Street West, 10th Floor, Toronto,  
Ontario, on Monday, January 28th, 1991,  
commencing at 10:30 a.m.

1 ---Upon commencing at 10:30 a.m.

2 MADAM CHAIR: Good morning. Please be  
3 seated.

4 Good morning.

5 THE WITNESS: Good morning.

6 MADAM CHAIR: Mr. Lindgren?

7 MR. LINDGREN: Good morning, Madam Chair  
8 and Mr. Martel.

9 MADAM CHAIR: Before we get started, Mr.  
10 Lindgren, there were two documents to be made exhibits  
11 this morning.

12 First is a memo we received on January  
13 the 25th from the Ministry of Natural Resources  
14 responding to the undertaking we gave them a week or so  
15 ago about transcript references to evidence on old  
16 growth forests in the MNR case.

17 And this document is five pages and we  
18 will assign it No. 1663.

19 ---EXHIBIT NO. 1663: Two-page MNR memo, response to  
20 undertaking re: references to  
21 previous MNR evidence on old  
growth forests.

22 MADAM CHAIR: And the second document is  
23 a letter that was sent to the Board by the Canadian  
24 Paperworkers Union dated January the 9th, a two-page  
25 letter, and Mr. Pascoe's response to that letter, and

1 another letter from Mr. Pascoe referring the Canadian  
2 Paperworkers Union letter to the Minister of the  
3 Environment.

4 And this package has four pages and we  
5 will label this Exhibit 1664.

6 ---EXHIBIT NO. 1664: Four-page document consisting of  
7 letter dated January 9, 1991 from  
8 CPU to EAB with EAB response and  
copy of EAB referral letter to  
Minister of Environment.

9 MS. BLASTORAH: Madam Chair, if I could,  
10 just for the purposes of clarification, I should point  
11 out to the other parties that the summary -- or the  
12 outline rather that was provided as Exhibit 1663 only  
13 dealt with the Ministry of Natural Resources' evidence  
14 and transcript references to the Ministry's evidence.

15 MADAM CHAIR: Thank you, Ms. Blastorah.

16 Okay. Mr. Lindgren, shall we begin with  
17 Mr. Maser. Welcome to Toronto.

18 THE WITNESS: Thank you.

19 MR. LINDGREN: Before we commence with  
20 Mr. Maser's evidence, Madam Chair, there are a few  
21 preliminary matters, not the least of which is marking  
22 a series of documents as exhibits.

23 I would suggest that we commence by  
24 marking the FFT witness estimate No. 6 as Exhibit 1665.

---EXHIBIT NO. 1665: Witness Statement for FFT Panel  
No. 6.

MR. LINDGREN: And following, that the next exhibit should be --

MR. MARTEL: Do want to slow down for a moment.

MR. LINDGREN: Sorry.

**MADAM CHAIR:** Okay, Mr. Lindgren.

MR. LINDGREN: The next exhibit to be marked is the CV for Mr. Maser.

MADAM CHAIR: That will be Exhibit 1666.

MR. LINDGREN: Thank you.

---EXHIBIT NO. 1666: CV of Chris Maser re: FFT Panel  
No. 6.

MR. LINDGREN: The next item to be marked is the supplementary source book which contains 77 photographs relating to Mr. Maser's evidence and it also contains an index to those photographs.

MADAM CHAIR: Okay. That's source book  
No. I.

MR. LINDGREN: It's entitled  
Supplementary Source Book.

MADAM CHAIR: These are the actual photographs. Yes, okay. That's Exhibit No. 1667.

MR. LINDGREN: Thank you.

---EXHIBIT NO. 1667: Supplementary Source Book re: FFT  
Panel No. 6.

MR. LINDGREN: Then we have three volumes of the documentary source book, and I would suggest that these be marked as Exhibit 1668A, B and C.

---EXHIBIT NO. 1668A: Documentary Source Book I re:  
FFT Panel No. 6.

---EXHIBIT NO. 1668B: Documentary Source Book II re:  
FFT Panel No. 6.

---EXHIBIT NO. 1668C: Documentary Source Book III re:  
FFT Panel No. 6.

MADAM CHAIR: Okay, Mr. Lindgren.

MR. LINDGREN: The next document to be marked as an exhibit is a source material entitled: Conservation Strategy for the Northern Spotted Owl, and it is by Jack Lord Thomas and others.

MADAM CHAIR: Okay. And that will be Exhibit 1669.

---EXHIBIT NO. 1669: Source material entitled:  
Conservation Strategy for the  
Northern Spotted Owl, by Jack  
Lord Thomas et al.

MR. LINDGREN: The next item, Madam  
Chair, is a copy of the Redesigned Forest, and I take  
it that will be Exhibit 1670?

MADAM CHAIR: Mm-hmm.

---EXHIBIT NO. 1670: Document entitled: Redesigned Forest.

MR. LINDGREN: And the final document, Madam Chair, I've placed on your desk this morning, this is an excerpt from the Wildlife Habitats and Managed Forest document and it's an excerpt containing Chapters 3, 4, 5 and 6 and appendices 11, 12, and 13 from that document.

MADAM CHAIR: That will be Exhibit 1671.

---EXHIBIT NO. 1671: Excerpts from Wildlife Habitats and Managed Forest document, containing Chapters 3, 4, 5 and 6, and Appendices 11, 12 and 13.

MR. LINDGREN: And those are all my documents at this time, Madam Chair. I would ask you to swear the witness.

MS. CRONK: Excuse me, Madam Chair.

Sorry to interrupt, could my friend clarify for us what Exhibit 1669 was again; and, secondly, whether copies have been made available?

MR. LINDGREN: Exhibit 1669 is a rather large document, Madam Chair, it's a document relating to the northern spotted owl. It was referred to in the witness statement -- or actually the reference was omitted but we subsequently filed the document and it has been filed with the Board for some time.

1                   We didn't make multiple copies available  
2                   to the parties, Madam Chair, because of the sheer size  
3                   of the document, Madam Chair, but it has been available  
4                   for coping or review if the parties had so wished.

5                   MADAM CHAIR: We received this document  
6                   December 10th, Ms. Cronk.

7                   MS. CRONK: That's fine, Madam Chair,  
8                   thank you. As long as my friend has a copy here, we  
9                   can get it today.

10                  MR. LINDGREN: That's the only copy,  
11                  Madam Chair.

12                  MADAM CHAIR: All right, thank you.

13                  MR. LINDGREN: The next order of  
14                  business, Madam Chair, is to swear Mr. Maser.

15                  MADAM CHAIR: Yes. Mr. Maser, could you  
16                  approach the Board, please.

17                  CHRIS MASER, Sworn

18                  MR. LINDGREN: Madam Chair, I would like  
19                  to begin by briefly reviewing Mr. Maser's CV which has  
20                  been marked as Exhibit 1666.

21                  It's not my intention to review it in any  
22                  detail, but there are a few items I would like to  
23                  highlight for the Board.

24                  DIRECT EXAMINATION BY MR. LINDGREN:

25                  Q. Do you have a copy of your CV, Mr.

1 Maser?

2 A. Yes.

3 MR. LINDGREN: Perhaps if I could, Mr.  
4 Maser, I'll lend your copy of the CV to Mr. Martel.  
5 I'm sure you're familiar with what's on the CV.  
6 (handed)

7 Q. Now, Mr. Maser, I understand that you  
8 received an undergraduate degree and a graduate degree  
9 in general science and zoology; is that correct?

10 A. Yes.

11 Q. And I understand that you've  
12 conducted biological and forestry field research for  
13 over 20 years, primarily in the temperate coniferous  
14 forests?

15 A. Yes.

16 Q. And have you studied the forests of  
17 other jurisdictions or other countries?

18 A. Yes, I worked in the forests in the  
19 Himalayas and I spent a couple of years in Europe in a  
20 boarding school and then went back in 1985 to look  
21 specifically at forest problems, and I worked in north  
22 Africa in places where there used to be forests, so  
23 I've seen what's happened all over there.

24 Q. Okay. And I understand that you've  
25 occasionally lectured in biology, forestry and ecology

1 at various colleges and universities throughout the  
2 United States?

3 A. That is correct, and Canada for that  
4 matter.

5 Q. Now, on page 1 of your CV there's a  
6 reference to your involvement with the Federal Research  
7 Natural Areas System for the U.S. Forest Service.

8 I'd ask you to briefly explain what a  
9 research natural area is, and can you briefly describe  
10 the nature of your work?

11 A. The Research Natural Area System was  
12 set up to protect undisturbed areas of the ecosystem or  
13 different parts of the ecosystem such as different  
14 forest types, grasslands, so that the generations of  
15 the future would have a chance to look back and see  
16 what we have done to the environment on the one hand.

17 On the other hand they were set aside for  
18 educational purposes and for non-destructive research  
19 purposes to monitor processes, ecological processes and  
20 see how humanity is impacting those processes.

21 It's an interagency organization and all  
22 of the agencies, the Bureau of Land Management, the  
23 U.S. Parks Service, U.S. Fish and Wildlife Service  
24 Refuges, the U.S. Forest Service have looked over their  
25 areas to see what types of parts of the ecosystems need

1 to be set aside.

2 And I think it was 19 -- I think it was  
3 1975, I forget, but we had a national meeting to take  
4 the northwest and look at what was out there, what did  
5 we have and what was missing, then try to fill in the  
6 pieces. We looked at it as an insurance policy for the  
7 future, I would say.

8 Q. And what do you mean by that?

9 A. If we liquidate all of the habitats  
10 for whatever reason and we make mistakes, then the  
11 future has no way to go back and find out whether what  
12 we did that was either right or wrong.

13 And there's some ecosystems, like in the  
14 Willamette Valley, the white oak ecosystem is gradually  
15 disappearing because there was very little of state  
16 lands and the farmers that own it have been cutting the  
17 oaks down for firewood for years and they're gradually  
18 disappearing.

19 You can think of it as John Magnusson  
20 calls the invisible present. They disappeared so  
21 gradually that over a decade all of a sudden we woke up  
22 and realized there's almost no white oak left, because  
23 during that decadal time frame no one was really paying  
24 attention.

25 So we thought, well, we have something,

1 we had best make sure that we set some aside and  
2 capture a few representatives while the opportunity was  
3 there.

4 Q. A few moments ago you referred to the  
5 Bureau of Land Management, and I understand that you  
6 worked for the Bureau for approximately 12 years.

7 Can you briefly explain what the Bureau  
8 of Land Management does and, again, can you briefly  
9 describe the nature of your work for the Bureau?

10 A. The Bureau of Land Management in  
11 essence got most of the land that the Forest Service  
12 didn't get. It was originally a -- it was originally  
13 the agency that gave land away in the homestead days,  
14 then it became the tailor of grazing service, where  
15 they adjudicated the grazing to make sure that they  
16 didn't overgraze the west, and gradually became the  
17 Bureau of Land Management.

18 The challenge in the beginning with the  
19 Bureau was it was simply custodial, they were holding  
20 the lands to give it away to private ownership and they  
21 were the lands like the deserts and the grasslands that  
22 no one saw a great value in.

23 In 1976 they got their own jurisdiction,  
24 and so now those lands are not to be given away and  
25 they are a full-fledged management agency. They

1 have -- for example, they take care of a lot of Alaska,  
2 particularly the fire. They own a lot of the -- they  
3 have jurisdiction over a lot of the west, they have  
4 jurisdiction over the outer continental shelf when it  
5 comes to oil drilling leases, they also are in charge  
6 of the mineral rights under a lot of the public lands  
7 and private lands on the east coast.

8 When they asked me to work for them it  
9 started out looking at range wildlife relationships and  
10 then it shifted to forest relationships because I was  
11 housed in a Forest Service research lab, and the reason  
12 for that was, I was the only research scientist that  
13 the Bureau had ever had and they didn't know what to do  
14 with me exactly, they just knew they needed some help.

15 And so I was housed with the Forest  
16 Service, and during that time there was -- we had a  
17 tremendous outbreak of bark beetles, and then three  
18 national forests came together and asked us to produce  
19 a document that would tell them how to manage the land,  
20 how to achieve what they wanted without destroying it,  
21 but not what to do, and that was where the Wildlife  
22 Habitats and Managed Range Forests came from.

23 Subsequently we did one for the Bureau of  
24 Land Management on managed habitats and wildlife  
25 habitats and managed rangelands.

1                   Q. Have you been involved with old  
2 growth research with either the Bureau of Land  
3 Management or the U.S. Forest Service?

4                   A. Yes. The last eight some years that  
5 I was with the Bureau of Land Management both they and  
6 Forest Service asked me specifically to move to the  
7 west side where I had come from to study the old growth  
8 forest issue, and that was what I spent the last eight,  
9 eight and half years of my research career doing  
10 specifically, was looking at old growth.

11                  Q. Now, on page 5 of your CV there's a  
12 reference to the fact that in 1986 you testified at the  
13 Weaver's Congressional Hearing on Old Growth. Can you  
14 briefly describe the nature of that hearing and the  
15 nature of your involvement in it?

16                  A. Congressman Weaver, as the  
17 congressional people do periodically, set up hearings  
18 so that, one, they can get a better idea of what is  
19 going on; and, two, to try and sift -- sort out what is  
20 going on between the struggle we have particularly in  
21 the northwest between the industrial view and the  
22 conservation view, and neither side has really dealt  
23 with the ecological view in the northwest; while the  
24 one fights over trees for this reason, the other fights  
25 over trees for that reason we're using the forest.

1                   And so I was asked to represent the  
2 middle, to represent the ecological view, and it was in  
3 that vein that I testified.

4                   Q. Your CV also indicates that you've  
5 served as a technical reviewer for a number of journals  
6 and publications including the Canadian Field  
7 Naturalist and the Canadian Journal of Zoology. Is  
8 that correct?

9                   A. Yes.

10                  Q. And I understand that you have also  
11 worked as an independent forestry consultant, and  
12 perhaps you can briefly describe the nature of your  
13 work as a consultant?

14                  A. What I found when I decided to get  
15 out of the government was that there was a tremendous  
16 lack of understanding of what we think we know about  
17 the ecology of the forested system.

18                  Scientists are not basically good at  
19 translating science for the average person. The  
20 conservationists are interested in their view, the  
21 industrialists are interested in their view, and they  
22 are all right from their points of view, but what was  
23 missing was some way of translating the scientific data  
24 that I've worked with with colleagues for so many  
25 years.

1                   At the same time the Forest Service came  
2                   along and said, we need to change but we don't know how  
3                   to do it and we know that what we're doing is no longer  
4                   working, we would like you to help us change. So what  
5                   I have spent a lot of time doing is putting on  
6                   workshops, going through what we understand about the  
7                   ecosystem, then we pick their problems, we go out into  
8                   the field and look at ways that we might solve those  
9                   problems.

10                   The other thing that I do is get the  
11                   industrialists, the conservationists, industry,  
12                   different industries like the cattle industry where  
13                   there is an impact from livestock grazing and the  
14                   Forest Service together and we go through a process of  
15                   conflict resolution, getting down to looking at the  
16                   forest and saying: How can we manage this so everybody  
17                   can benefit, because the constant in-fighting is  
18                   gradually destroying the system. There has to be a  
19                   better way for people to deal with one another, and  
20                   that -- I do a lot of that.

21                   Q. And I assume that you currently work  
22                   with the U.S. Environmental Protection Agency as a  
23                   landscape ecologist. Can you briefly describe what is  
24                   meant by the term landscape ecology, and can you  
25                   explain what you're doing for that agency?

1                   A. I gave the Environmental Protection  
2     Agency one year. They asked me if I would help them --  
3     let me back up for a second. They have a new program,  
4     relatively new, called environmental monitoring  
5     assessment program and it's gotten off to a rocky start  
6     because most people look at land from a product base  
7     which gives whatever research questions we ask a human  
8     value, a slant of a human value whichs tend to hide the  
9     ecological relationships or misrepresent them in many  
10    cases.

11                   So the Environmental Protection Agency  
12    first wrote and asked me if I would be willing to help  
13    them. Then I said: No. Then they called and I said:  
14    No, and finally I was persuaded. So I gave them a  
15    year, they gave me the title of landscape ecologist,  
16    which is not really what I'm doing, what I'm doing is  
17    helping them to refocus their programs so that they are  
18    in fact measuring and monitoring those things that are  
19    necessary to have as unbiased a view as possible of the  
20    changes that are taking place in the landscape either  
21    what they call natural changes or changes caused by  
22    human beings and then, secondarily, to look at the  
23    product output that society would like and see what  
24    impacts we're having on that.

25                   Q. Now, attached to your CV we see a

1 publication list of approximately 200 publications. Is  
2 this a fairly complete or up-to-date list?

3 A. It's something over 200 at this  
4 point.

5 Q. There are a couple that I would like  
6 to highlight and ask you about.

7 I understand that you are co-author  
8 actually of the Wildlife Habitats and Managed Forests  
9 and in fact you're a co-author of the chapters that  
10 have been filed as Exhibit 1671.

11 Can you explain how you came to be  
12 involved in this particular project?

13 A. Yes. Jack Thomas, who was the man in  
14 charge of the lab that I was working, the Forest  
15 Service lab in La Grande when I started working for the  
16 Bureau of Land Management, was the gentleman who was  
17 approached when the three national forests that they  
18 called the Iron Triangle in northeastern Oregon,  
19 realized they were going to have to deal with the  
20 insect infestation and they were very concerned about  
21 not having enough data that when they started dealing  
22 with the beetle-killed timber they would do severely  
23 ecological damage.

24 Jack is trained as a big game biologist,  
25 and so his basic understanding of the ecosystem was

1 fairly limited and so he approached me and asked if he  
2 could borrow three days of my time for the Bureau of  
3 Land Management to help them put together an outline  
4 for a book and how it would have to be done, and that  
5 three days ended in 1979, so it took four years.

6 Q. And I understand that you did similar  
7 work for the rangelands in southeast Oregon?

8 A. Yes, we did.

9 Q. And you're also the author of the  
10 Redesigned Forest which has been marked as Exhibit  
11 1670?

12 A. Yes.

13 Q. Publication No. 170 on your list is  
14 the document entitled: From the Forest to the Sea.  
15 And that has been reproduced, Madam Chair, in Volume I  
16 of the source book.

17 Did you have any comments as to that  
18 document?

19 A. That was the last official government  
20 report that I wrote -- I was part of writing. That was  
21 a culmination of basically the eight or nine years that  
22 I spent at the Corvallis lab working on old growth  
23 forest.

24 We synthesized everything that we could  
25 get our hands on at that time so that we hoped an

1 average reader would have a better understanding of  
2 what the issues were and a better understanding of how  
3 the system functioned based on what we knew today.

4 Q. And then finally, Mr. Maser,  
5 publication No. 194 on your CV list - this is on the  
6 last page of the document, Madam Chair - there's  
7 reference to your participation at an old growth  
8 conference held here in Toronto last year.

9 And can you briefly describe the nature  
10 of your participation in that event?

11 A. They invited a group of people to  
12 come to university and speak on old growth, trying to  
13 help the public to characterize what old growth was and  
14 was to them, and my charge was to deal with the basic  
15 ecological relationships. That publication has since  
16 come out.

17 MR. LINDGREN: Madam Chair, those are all  
18 the questions I intend to put to Mr. Maser about his  
19 CV, and I would move that Mr. Maser be qualified as an  
20 expert in forest ecology, wildlife biology, landscape  
21 ecology, forest management.

22 MR. MARTEL: Do you want to repeat them?

23 MR. LINDGREN: Yes. We're moving that  
24 Mr. Maser be qualified as an expert in forest ecology,  
25 wildlife biology, landscape ecology, forest management,

1 and the human interactions within and between landscape  
2 and management.

3 MADAM CHAIR: Are there any objections to  
4 Mr. Maser being qualified in this way?

5 MS. CRONK: I have no objections, Madam  
6 Chair, but I will have some questions with respect to  
7 those suggested areas of expertise.

8 MADAM CHAIR: Fine. All right, then Mr.  
9 Maser is so qualified.

10 MR. LINDGREN: Thank you, Madam Chair.

11 Q. Now, Mr. Maser, I would like to ask  
12 you to start by briefly outlining the basic message of  
13 your evidence for the Board.

14 A. This is not an ecological message  
15 that I'm going to give you, this is a view that I think  
16 we all need to adopt if we're going to resolve any one  
17 of these problems anywhere in the world.

18 When Jonas Salk, who was given  
19 commendation for developing the Salk vaccine, he was  
20 asked how it felt to have that scientific breakthrough  
21 and he said:

22 "There's no such thing."

23 The point that he made that stuck with  
24 me - because I heard this as a young person - was that:

25 "I had one piece of the puzzle...", he

1       said,

2                       "...and I had no place to put it if it  
3                       hadn't been for the thousands of other  
4                       people who had put their pieces in first  
5                       that none of us had ever heard of."

6                       The other thing I've learned over time in  
7       courtrooms also is that I can't convince anyone of  
8       anything, including you, without convincing you -- for  
9       me to convince you I'm right, I must simultaneously  
10      convince you that you're wrong. At that point I have  
11      already stole your dignity and you can no longer hear  
12      what I say, therefore, I'd never try to convince anyone  
13      of anything.

14                      What I bring is simply a gift of ideas,  
15      of data research and how we put it together and how we  
16      think we see the world, understanding that everything  
17      we do is but a working hypothesis, because the best  
18      that science can do is look at, measure, judge and  
19      interpret the apparent defects. We're not very good at  
20      getting at the causes.

21                      I once gave a speech at the University of  
22      British Columbia in which I said that I didn't know  
23      scientific truth and I wouldn't if I stepped on it  
24      because I don't know a scientific lie. I still feel  
25      that way. The longer I've studied the systems, the

1 less I know about the systems; though we know a great  
2 deal, we really know very little.

3 There are a lot of things out there that  
4 we can't even identify, let alone begin to understand  
5 how they interact. So at best what I bring, to my  
6 mind, is a simplistic view of how the system works.

7 This brings me to a consideration of a  
8 comment Albert Einstein said at the end of World War I  
9 that:

10 "Science can no longer operate in  
11 intellectual isolation."

12 He realized that his struggle became that  
13 he was responsible for Nagasaki and Hiroshima, not  
14 because he had any idea of the bomb, but because he  
15 gave society the formula that led to the bomb. And his  
16 point was - and it is well taken, and even more so  
17 today - his point was that, we are responsible for the  
18 outcomes of our actions, whether scientific or  
19 otherwise. We can no longer isolate ourselves from the  
20 impacts we impose on society.

21 And as I look at what has been done to  
22 the environment in the name of science, there has been  
23 a tremendous amount of degradation because we have not  
24 yet learned that lesson.

25 I'm very uncomfortable ever being labeled

1 as an expert because to me an expert is someone who  
2 thinks he or she knows what the right answers should be  
3 and at that point can no longer see what the answer  
4 might be.

5 I think of it more that we need a  
6 beginner's mind which looks at the world as open  
7 mindedly as possible, ready to accept change and see  
8 what the answers might be because I do not find right  
9 or wrong answers.

10 And this is my point. If there is a  
11 river like we have in the United States, this is a  
12 river flowing this way, and this is a pulp mill, and  
13 the intake water comes up here and the effluent comes  
14 out down here and is polluting the river with dioxins,  
15 the normal struggle takes place inside here with the  
16 regulatory agency arguing with the pulp industry to  
17 clean up the river.

18 A simple solution, if we think beyond the  
19 norm, is not to argue about it but insist that the pulp  
20 mill put their intake below their output. At that  
21 point they are impacting themselves and will have to  
22 clean up their own act.

23 That is simply looking at the same thing  
24 with the beginner's mind and not getting stuck on the  
25 traditional view. The traditional view will slowly

1       destroy a lot of what the world has to offer. It has  
2       not worked in the past, it is not working today; we  
3       need to look at things differently.

4               Sitting Bull at the end of the Battle of  
5       the Little Big Horn told his people:

6               "Do not shun the white man's road because  
7               you must travel it. So take from it that  
8               which is good and keep it and discard the  
9               rest."

10              And he said:

11              "Our old ways are not all good either, so  
12              take from them that which is good and  
13              discard the rest and understand that you  
14              are renegotiating the reality of the  
15              future."

16              That is what we must do. These endless  
17       arguments between industry and the conservationists and  
18       this side and that side, while they argue about who  
19       gets what for what, we gradually lose the forest. We  
20       need to come together with a different reality of how  
21       we look at the world, we need to renegotiate that.

22              I have been in court, to my mind too  
23       often, and I find - as the last resort - but I find we  
24       either go to court to punish or to teach, and this is  
25       what I would like you to keep in mind.

1                   If we go to court to punish and we win,  
2           what have we won? We have won the legal right to  
3           remain stuck within the rigid limits of our thinking;  
4           we have won the legal right to argue for and retain our  
5           fear of change and inner growth as human beings and we  
6           argue for our limitations at the expense of our  
7           potential.

8                   If we wine, what have we won? We have  
9           won the legal right to humiliate our opponent because  
10          the court has awarded us our opponent's dignity, which  
11          is a legal trophy of conquest.

12                   On the other hand, if we go to court to  
13          teach we are all winners because we're able to face one  
14          another with the courage to examine the issue, to allow  
15          each other the dignity to change without coercion and  
16          to help each other experience each other as we grow the  
17          process toward a new understanding and a new  
18          relationship in a viable resolution, the product, in  
19          which all parties emerge with at least a portion of  
20          their needs met. And the lawyers have the moral and  
21          ethical duty to truly act as legal counsel, not as  
22          generals in a futile endless battle, then all sides can  
23          emerge as winners with their dignity intact, the only  
24          way humanity can truly win.

25                   As I look at the world today I find there

1 are no longer individual winners and losers, humanity  
2 today wins or loses together. What you do to your  
3 forests in Ontario, what we do to them in Oregon  
4 affects the world as a whole, therefore, we are each  
5 other's keepers and we must act the part.

6 Q. I would like to turn now to the  
7 content of your witness statement. The statement  
8 itself is entitled: Economically Sustained Yield  
9 Versus Ecologically Sustainable Forest Including Old  
10 Growth.

11 I would like to ask you to explain what  
12 you mean by the phrase ecologically sustainable forest  
13 or ecologically sustainable forestry?

14 A. Something which is ecologically  
15 sustainable looks at what is necessary to maintain its  
16 integrity in an ecological or biological sense.

17 That, unfortunately, is not the focus of  
18 western society. Our focus is on the products and,  
19 therefore, we cease to see the forest.

20 Where you're sitting, if you look out  
21 here, you see the entire room, so you see everything in  
22 relationship, but the moment you look down to write  
23 your focus becomes limited and the room goes out of  
24 focus. When you look at the room you're dealing with  
25 the same as the forest in relationship, but when you

1 look down at the paper you're dealing with the product.  
2 We have become so product oriented that we have lost  
3 sight of the forest, so we deal with the products and  
4 not the processes.

5 Ecological sustainability looks out for  
6 the health and the sustainability, the ability of the  
7 forest to exist in a vital estate first and foremost,  
8 and then removes the products as the forest gives us  
9 the capability to do so.

10 Q. Perhaps I could ask you to slow down  
11 a little bit because some of us do have to take notes,  
12 notwithstanding our product oriented focus.

13 How does the concept of ecologically  
14 sustainable forestry differ from what you've termed  
15 economically sustained yield?

16 A. In the United States we have a law  
17 called the Multiple Use Sustained Yield Act. That was  
18 not the intent of Congress; Congress meant sustainable  
19 but they wrote sustained, which is the way it has been  
20 interpreted.

21 To sustain something at a given level is  
22 to make sure that it stays the same. They have even  
23 gone so far as to call it non-declining even flow. In  
24 reality what we're sustaining is not the ability of the  
25 forest to grow wood, what we are sustaining is the cut

1 of old growth. In fact we have upped that over the  
2 years. It used to be in the Willamette National Forest  
3 that when they cut out the big, big trees in the bottom  
4 they cut a certain volume and a certain number of  
5 acreages. In order to maintain the sustained yield of  
6 wood volume at higher elevations - which we've been  
7 doing since 1960 or so - they are cutting five times  
8 the acres to get the same volume of wood. That is  
9 sustained yield, that is an economic concept that has  
10 nothing to do with the biology of the forest.

11 Sustainable yield, on the other hand,  
12 would be removing from the forest on a sustainable  
13 basis that which the forest can give without impairing  
14 its ability to function and to in fact replenish  
15 itself, because the forest is more than just the trees.  
16 We have been focused on the trees and the sustained  
17 yield of wood fiber, period.

18 Q. Sustained yield has received a great  
19 deal of attention in this hearing, as you may know, Mr.  
20 Maser. I would like to put to you a phrase or an  
21 excerpt from the Class Environmental Assessment  
22 Document. And I'm am reading from page 97, Madam  
23 Chair, of the Class EA Document which is marked as  
24 Exhibit 4.

25 And on that page, Mr. Maser, there's a

1 discussion of the concept of normal forest. And  
2 further down that page it says:

3 "In Ontario's forests, where such  
4 conditions never exist, the practical  
5 meaning of sustained yield is continuity  
6 of harvest."

7 And on the next page, on page 98 of the  
8 Class EA, there's a statement that:

9 "Timber management is aimed at  
10 the organization of the forest to bring  
11 about this sustained yield of wood  
12 products in an efficient and orderly  
13 manner."

14 Do those statements reflect the problems  
15 that you have described with respect to sustained yield  
16 management?

17 A. Yes, they do. That is a product  
18 orientation, not a process orientation.

19 Q. And Forests for Tomorrow has proposed  
20 terms and conditions that stipulate that all  
21 silvicultural prescriptions in this province must  
22 provide for the ecological sustainability of the  
23 forest. Is that an objective that you would support?

24 A. Yes.

25 Q. Now, in order to practice

1 ecologically sustainable forestry, is it necessary to  
2 determine the ecological capability of the forest?

3 A. Yes, it is.

4 Q. And in general terms --

5 A. Particularly over time.

6 Q. And how would one go about doing  
7 that?

8 A. Well, we have spent a lot of years  
9 studying the forest, trying to figure out how different  
10 parts, components of it function because one of the  
11 things that we discovered fairly early on was that if  
12 you look at the forest from a strictly economic view  
13 everything that is not used by the human being is a  
14 waste; it is an economic waste however, it's not a  
15 biological or ecological waste. In a system that is  
16 functioning ecologically, there is no such thing as  
17 ecological waste, everything is recycled.

18 The challenge we face is in the  
19 Linearity of our thinking. Maybe I can use - I don't  
20 have it drawn out here, but if you will permit me, I  
21 will try and explain what I mean by the linearity.

22 And there are two ways of looking at any  
23 system; one is to see the system as a cycle, and the  
24 other is in thinking of looking at the thinking as a  
25 straight line, and this is the western European mode of

1 thinking.

2 And what that means is that when we  
3 looked at the forests originally, as we look at them in  
4 the United States today, we see production as --  
5 production is okay - it's on this part of the cycling  
6 axle - production is here, decline is here, decline is  
7 not okay in yield.

8 In other words, the industry is not  
9 considered or our nation -- our gross national product  
10 is not considered healthy unless it's always expanding.  
11 You cannot continue to expand with what ultimately are  
12 limited resources, and a forest or trees are renewable  
13 in a sense but, over time, if we do not take care of  
14 the soil and all of the other components that create  
15 the forest, what we end up are limited resources, they  
16 are ultimately finite if we do not allow for their  
17 sustainability.

18 For example, if you have like a cake  
19 mix - if you ever baked a cake from scratch - there are  
20 certain ingredients that you put together and you know  
21 what they are, you know how they measure up and you  
22 learn what they do because if you leave one out, like  
23 baking powder, the cake doesn't do very well. That is  
24 looking at and understanding the system, the processes.

25 When we look at the forest today we look

1 at it like a cake mix and when you get a box of cake  
2 mix, if you pour it on the table you still have  
3 ingredients and then you add the other ingredients:  
4 egg, oil, milk, whatever; it still isn't a cake until  
5 you add the heat.

6 And this is the part that we forget when  
7 we look only at managing the forest for products, is  
8 that forests are not trees, they're the interactions of  
9 soil, water, air and sunlight, the chemical  
10 interactions, and if we do not take care of that part  
11 of the system then we simply will not have a forest;  
12 like if you do not add heat to this pile of  
13 ingredients, you cannot have a cake.

14 In linear thinking, which originated in  
15 forest management in Europe with the Germans, they saw  
16 it as a straight line because they built it on the land  
17 rent theory, which was an economic theory which stated  
18 that it is best to take the kind of tree that grows  
19 fastest and best on the site so you get the maximum  
20 yield for the minimum amount of economic input into the  
21 system.

22 And in their time that was right because  
23 what they were doing was healing forests, repairing  
24 those that had been devastated by wars, use of wood for  
25 energy, et cetera.

1                   We adopted that in the United States with  
2       Gifford Pinchot who was trained in British colonial  
3       forestry in France. It's a utilitarian view of the  
4       system. And there was nothing wrong with it in the  
5       early days, except what we found is: If we do not  
6       allow the system to go full cycle, it becomes  
7       exhaustive and the system no longer produces the way it  
8       did, which in one of the references I sent up, Dr.  
9       Richard Plochmann, who is a German forester, has  
10      finally -- they finally reached the point where they're  
11      understanding this because they have been measuring the  
12      second and third rotations and they're finding by the  
13      end of the second rotation they may have lost 20 to 30  
14      per cent of the productivity, because what they didn't  
15      do was take care of the soil first; what they did was  
16      focus on the product so much that they lost sight of  
17      the process and the system.

18                   And we in the United States are facing  
19      the same thing, in fact world forestry is still looking  
20      at it in a product mode, and so we all face that  
21      problem.

22                   Q. Mr. Maser, if production targets are  
23      set as a matter of policy and they're not based on the  
24      ecological capability of the forest, can it be said  
25      that you're practising ecologically sustainable

1 forestry?

2 A. No. And my basic concern with  
3 ecologically sustainable forestry is that I will always  
4 argue for an economically sustainable industry, but  
5 industrial economic sustainability can only happen if  
6 we first have an ecologically sustainable basis of the  
7 forest on which to secure the economically sustainable  
8 industry.

9 Let me put it one other way. To have --  
10 the foundation is the ecological sustainability of the  
11 system, on that is built the economic sustainability of  
12 industry, on that is built the economic sustainability  
13 of the community, on that is built the economic  
14 sustainability of society. If we destroy the  
15 foundation on which this whole human drama is enacted,  
16 everything else will crumble like a house of cards.

17 Q. Does the ecological capability of a  
18 forestry remain constant?

19 A. No, it doesn't, and we may be  
20 rewriting all of the rules of global greenhouse  
21 warming.

22 Q. And if the ecological capability does  
23 not remain static, how does one go about dealing with  
24 changes such as global warming?

25 A. Well, to enter that I'm going to have

1 to give you a brief overview of how we think the system  
2 works, so I can put this in perspective.

3 MR. LINDGREN: Madam Chair, I would  
4 suggest that once Mr. Maser has completed his review of  
5 the flip charts we'll mark them all as an exhibit.

6 MADAM CHAIR: All right, Mr. Lindgren.

7 THE WITNESS: Can you see okay?

8 MADAM CHAIR: Yes, fine, Mr. Maser.

9 THE WITNESS: Can you see, sir?

10 MR. MARTEL: I can see it, the only  
11 problem is that--

12 MADAM CHAIR: He couldn't see through  
13 you, Mr. Maser.

14 MR. MARTEL: --I couldn't see through  
15 you, I'm afraid.

16 THE WITNESS: Oh, that's what I was  
17 concerned about.

18 MR. MARTEL: A slight problem.

19 THE WITNESS: That's why I wanted to move  
20 this. Can you see it now, sir?

21 MR. MARTEL: Yes.

22 THE WITNESS: Okay. If we look at a  
23 geographical area of the world, you can pick any area  
24 you want to because so far as we have been able to  
25 determine they all function somewhat the same.

1           There appears what we would called Gaia,  
2   the Gaia Principle, which is the earth's surface as a  
3   whole. Pick a geographical area. There are four  
4   things which limit what that area can do in responding  
5   ecologically; the first one is the geology of the area,  
6   we would consider that to be the hard limits, that sets  
7   the stage for everything that happens inside.

8           The geology in large measure determines  
9   the macroclimate, the overall climate; those two  
10   together determine the topography, and that is also  
11   then determined by the parent material, which is the  
12   original rocks from the geological process, those are  
13   the hard limits; and within those limits are then  
14   determined what we call the three soft limits, the  
15   disturbance regimes such as fire or earth flows, things  
16   like that. That in effect -- that affects the  
17   hydrology which in turn determines a lot of the  
18   microclimate, the topographical microclimate.

19          Now, these three things are flexible and  
20   they change over time - over the short run,  
21   geologically speaking - and they are controlled by  
22   these hard outer limits.

23          The next layer would be the soil. The  
24   soil is the placenta of the earth in a sense, it's the  
25   membrane which is both living and non-living, it

1 integrates the parent material with living organisms,  
2 so it is a membrane of continuity between the two.

3 Within this system are the individual  
4 organisms which make up the species, which collectively  
5 create the communities, which collectively create the  
6 landscape that we then divide up in our minds and call  
7 ecosystems, and ecosystem is an arbitrary term, to take  
8 out a segment of the landscape and say we are going to  
9 study this in its integrity, that is what we call an  
10 ecosystem.

11 I had a lot of problem with that because  
12 to me the world is an ecosystem, but if you divide out  
13 a small area that would be considered an ecosystem.

14 The culmination of all of this geological  
15 activity over time is this little central area that you  
16 can think of as a ball, this blue ball here in the  
17 middle, that is the condition that we inherit as human  
18 beings.

19 Now, the point that I would like to make  
20 is, and the point in science and in the monitoring  
21 effort the Environmental Protection Agency is making,  
22 is that this system must be viewed as value neutral;  
23 nature does not assign values to ecological processes,  
24 only human beings do that, and it is a real struggle to  
25 be unbiased, in fact I don't think the human being can

1 be unbiased, I do not think we can hold an unbiased  
2 thought.

3 But if we look at and study these  
4 processes, as we have been doing, outside the realm of  
5 product, outside the realm of conservation, outside the  
6 realm of industry, we have been trying to understand  
7 how these things influence one another because  
8 individuals collectively can influence the species,  
9 they influence the community, et cetera, this is in a  
10 constant flux, it is never the same.

11 What we are constantly trying to do is  
12 predict the interactions that go on here. What we can  
13 as a species, as individuals that become a species,  
14 that become human communities that affect the  
15 landscape, we are changing this hard limit, the  
16 macroclimate with global warming, and because we have  
17 the ability to impact this part of the system, as  
18 Einstein pointed out - and since World War II, I might  
19 add, we have the ecological and technological  
20 capability to completely disarrange the world's  
21 ecosystem - as we are doing with macroclimate.

22 That is going to shift all of these other  
23 parameters, and we don't know how that's going to react  
24 because it will be an unprecedented warming based on  
25 all of the predictions.

1                   So the thing to keep in mind is initially  
2 we must look at the ecosystem and study it as though it  
3 has no values, it is, and whatever it does you can say  
4 it's beneficial to some parts of it and detrimental to  
5 others.

6                   The other point is that over geological  
7 time and in most of the discussions I've had that have  
8 centered on the conservation controversy, time is an  
9 element that is excluded. We cannot exclude it,  
10 because we may have inherited the system here that's  
11 been here, it's been all over the map over time, so  
12 what we inherit is a dynamic system which is constantly  
13 changing. It is not a constant in time or space, but  
14 we look at it in both time and space and we think of it  
15 as a constant, particularly forests because they're the  
16 oldest living things on earth and they do not appear to  
17 change much, but if you have a thousand year old tree,  
18 that is several human generations that have lived and  
19 died within the lifespan of that tree.

20                  So then we had to figure out: Now, how  
21 do we deal with culture in all of this, and so we  
22 superimpose culture over the top of it. The blue ball,  
23 what we inherited, are the natural limits. Now, this  
24 is where the value is added and this is human value  
25 which very often cannot be equated to dollars and

1 cents.

2 But there's something interesting that  
3 happens when humanity imposes its value on the  
4 landscape, and we could look at the same acres. The  
5 pattern of human thought, in this case cyclic, which is  
6 process thinking, which is the way the native Canadians  
7 viewed the land, gives you a culture that is based  
8 primarily on religion and sees the entire landscape as  
9 a thou, that which is holy, that which is to be revered  
10 and to be part of.

11 What the native Canadians and the native  
12 Americans are still practising, more so - not like they  
13 used to, but more so than a lot of the rest of us - is  
14 understanding the real concept of resource. Resource  
15 as it was originally defined was a reciprocal  
16 relationship between humanity and the earth, to be the  
17 source of again, to resource, to give something back  
18 for what has been used.

19 If you look in the dictionary today  
20 resource is defined as a way a nation measures its  
21 wealth, something to be converted into money. In other  
22 words, what is out there is not okay, it has no value  
23 unless it is converted into dollars.

24 If you go back to the way the natives  
25 tend to see us still, religion underneath and then

1 comes economics and institutions, and this whole set of  
2 circumstances defines their survival as a culture.

3 If you look at our traditional western  
4 way of looking at the system, our economic view, the  
5 pattern of human thought is linear and, therefore, it  
6 focuses on products. We want to straighten out the  
7 system and whatever it is out there has no value unless  
8 it can be translated somehow into money through a  
9 product.

10 Our culture then has economics first,  
11 then the institutions, and religion is last, and it is  
12 an it, it is a commodity, something to be converted  
13 into money, we do not see the land anymore as holy, and  
14 all you have to do is look at what institutions  
15 dominate Toronto; the churches in stature or the  
16 buildings that deal with economics. That gives you a  
17 clue of what our thinking is.

18 Now, neither of this is right or wrong,  
19 good or bad. The point I'm making is that whatever  
20 your thought process is in this configuration, that is  
21 what will be imposed on the landscape, and so the two  
22 things that make the difference are the thought  
23 patterns, how we view the landscape. That is the  
24 reality with which we have negotiated with nature.

25 On the one hand the capitalistic --

1 straight capitalistic system, without a great deal of  
2 humility - which I would say of science and technology  
3 also - has the capacity to destroy the system because  
4 it sees it in the linear product mode.

5 On the other hand, the native view is not  
6 necessarily the panacea either, we need to combine the  
7 two. And there's a way of doing that, but to do that  
8 we must understand that the ecosystem siphons. Now,  
9 that doesn't mean it's a neat circle and it doesn't  
10 mean that you can't have things like plantations. It  
11 depends how it's done and with the attitude with which  
12 it's done.

13 For example, if you look at this, this is  
14 a cycle, and there's a linear part over on this side,  
15 it's a fairly straight line. The reason it's a cycle -  
16 and it can be any configuration - is because it comes  
17 back in time and approximates its beginning. That is  
18 the critical point.

19 Left alone nature may burn a thousand  
20 acres and it will grow for 30 years and it gets burned  
21 again and burned again, but ultimately in time it is  
22 allowed to come back to approximate its beginning  
23 through the old growth process, through succession, and  
24 then again it can be -- it is cycled and cropped.

25 Now, how it cycles is determined by the

1 geology, topography, parent material, the macroclimate,  
2 the hard outer limits. Within that is the play of the  
3 disturbance regimes such as fire, hydrology,  
4 microclimate and then the soil.

5           Within that are the individuals, the  
6 species, the communities and the microclimate which are  
7 pushing and nudging against those limits. So while  
8 this one may remain relatively fixed; this one is  
9 squishy and can move around and there's a constant  
10 interplay between these soft inter limits and the  
11 organisms that make up that cycle.

12           But the key is that it must come back and  
13 approximate its beginning or the processes do not  
14 function, because this cycle, this area of the  
15 landscape, if you look at it ecologically, is a living  
16 organism.

17           It's no different than my leg. If I  
18 break my leg skiing and I go to the doctor, he can put  
19 a pin in it and he can put screws in it and he can put  
20 a cast on it, but he can't heal it.

21           We found that we can't fix the forest no  
22 more than a doctor can fix my leg. We disrupt the  
23 processes as part of management, that's is okay; we  
24 break part of the system, that's okay; but we can't fix  
25 it because it's a living organism.

1           What we can do is plan in our management  
2   enough time to allow it to heal so that it can be  
3   cropped again. So what we're doing in essence, through  
4   allowing it to cycle all the way, is replenishing the  
5   soil nutrient capital, allowing the processes to heal  
6   so that once again at some point in the future it can  
7   be cropped, it can be used, and then by allowing it to  
8   rest and rejuvenate, we are being the source of its  
9   survival and ability to be used again.

10           This is an important concept because  
11   ecosystems, as are societies, are self-organizing  
12   cycles, they're self-organizing entities, and what I  
13   mean by that is, a forest will remain a forest so long  
14   as, for example, soil fertility, soil organic material  
15   and soil processes are not degraded to the point that  
16   it loses its vitality as a forest. We have lost many  
17   acres in the United States. What happens with most  
18   cycles is that they go around, and if you think of  
19   this -- are you familiar with bob sleds by any chance?

20           MADAM CHAIR: We know what they are.

21           THE WITNESS: Okay. If you think of this  
22   as the bob sled track, two of them together, they can  
23   be circles or they can be some other shape, but they  
24   have to touch so that there's a common boundary. If  
25   the bob sled here goes around and around, what happens

1 is in a system it tends to go a little bit faster than  
2 just holding its own, so it would creep up the side.

3 A self-organizing system organizes itself  
4 to a critical point and then there's a catastrophe  
5 which sets the system over and re-organizes it again,  
6 and all of the systems that we know of act this way,  
7 including earthquakes.

8 So if you think of this as a forest and  
9 it goes around and around and the bob sled climbs to  
10 the edge, all of a sudden it flips over the top and it  
11 starts cycling this way and re-organizing, you may have  
12 a grassland or shrub field.

13 If we do not keep this forest cycling  
14 within the limits of forest, we can flip it over the  
15 top and end up with shrub field or grassland which now  
16 does not produce trees, potentially it can, but we have  
17 found from some of our mistakes that the energy it  
18 takes in human years, in investment of fertilizers,  
19 silvicultural techniques and so forth to get this back  
20 into forest is incredible and it's far more costly than  
21 if we had kept it cycling within the purview of the  
22 forested ecosystem to begin with.

23 So understanding how this cycles and  
24 keeping it within that purview is much less expensive,  
25 particularly for the generations of the future.

1                   Systems, as we understand them, are like  
2 balls up here. There really is no such thing as  
3 ecosystem stability as far as we can determine, it's  
4 constantly being rocked back and forth up on this  
5 little nob. Now, what happens is periodically we push  
6 it off, we shove it down. Let's say, we suppress fire,  
7 if we suppress fire long enough we build up fuel loads,  
8 et cetera, all of a sudden rather than the normal  
9 creeping ground fires - which I'll talk about a little  
10 later - we have one which is a real blow out and it  
11 really burns fire.

12                   Now, what that has done is pushed the  
13 forest down here into a shrub field, and may stay as  
14 softwoods, go to hardwoods, it may be there for years,  
15 but given enough time it will recoup and will gradually  
16 go back to a conifer forest.

17                   But if we do this with something like  
18 global greenhouse warming or soil exhaustion as they  
19 have done in places in China, then what we do is we  
20 push the ball over here and it gets down in this trough  
21 and it cannot get out. This is probably the most  
22 stable part of the system, such as our deserts which  
23 used to be grasslands and we overgrazed with livestock  
24 in the southwestern U.S. They are far more stable now  
25 and less productive than they were, and the tendency

1 we've found is for these systems to go down, and if  
2 they cannot go back up, then they have lost  
3 productivity and the spiral is down.

4 Now, we have done this in a number of  
5 areas, and the reason we've done this is that we have  
6 focussed so hard on the product that we didn't  
7 understand the processes.

8 There's something that's important about  
9 that concept and this has taken us a long time to  
10 understand. There's a lot of talk these days about  
11 biodiversity and the loss of species. I would submit  
12 that that is not nearly so important as the  
13 introduction of things into the system that it has not  
14 evolved to handle; for example, substances.

15 In the United States we used to hunt with  
16 lead, I don't know -- hunt ducks with lead shot. I  
17 don't know what you folks use up here. But we found  
18 that the lead collected in the lakes as a foreign  
19 substance that the system was not equipped to deal with  
20 and the tremendous lead poisoning of the ducks during  
21 the non-hunting season because they were picking it up  
22 off the bottom. The system couldn't deal with that, so  
23 we began to lose ducks, individuals, whole populations.  
24 It endangered the Pacific northwest flyway of some  
25 species.

1                   Then there was the introduction of  
2   foreign practices or processes, and one of those would  
3   be clearcutting, one of those would be roading, and  
4   there's nothing wrong inherently with clearcutting or  
5   roading, but the thing to keep in mind is the system,  
6   it has not evolved to deal with these practices, and so  
7   what we are now doing is shifting the way that whole  
8   system functions.

9                   The other thing is technology. We are  
10   imposing on the system a technology and a thought  
11   process that goes with the technology to which the  
12   system has never before been subjected. We are  
13   changing the system, having a greater impact, by  
14   introducing things that are foreign to the system than  
15   we are by removing some of the pieces, but those pieces  
16   that are removed are all removed, so far as I can  
17   determine, by what we introduce.

18                  So we have come to the conclusion that  
19   the introductions of foreign things have a greater  
20   impact on the system, like radiation, in large doses.

21                  When Chernobyl blew up in 19 -- whenever  
22   it was, a few years ago, that had tremendous impact,  
23   but there was some buried dump that blew up in the  
24   Southern Ural Mountains in 1957 or '58 that sterilized  
25   roughly 1,000 square kilometres and it vaporized off

1 the face of this earth villages and people and animals,  
2 orchards, et cetera. That is what I mean by  
3 introducing something foreign which then disrupts the  
4 system's ability to function. The Russian scientists  
5 to the best of their ability think that area will be  
6 sterile for centuries.

7 The other thing we found then that  
8 whatever we introduce like that ultimately has greater  
9 impact than taking something away. Fire suppression is  
10 taking away a process of fire.

11 Now, we can have an impact on the forest,  
12 but if we reintroduce the fire that is a reversible  
13 process and everything over time, if you remove time as  
14 an element, everything in the earth is reversible to  
15 some point, but the system may never go back to what it  
16 was; and the system will heal itself, but we are  
17 looking at this in practical human terms, and so we  
18 have to be clear on the time lines we are talking  
19 about.

20 So if you take away fire suppression, you  
21 can have the system heal in a few years by  
22 reintroducing it, you can bring the system back closer  
23 to what it was.

24 Foreign in this sense to me means that  
25 something has been introduced into the system to which

1 the system is not adapted to deal with at the moment  
2 but, given enough time, it can probably adapt. For us  
3 the question is: Will humanity have enough time for  
4 the system to adapt before we have destroyed that which  
5 we have.

6 Now, if you think of the ecosystem as a  
7 milking stool - you're familiar with the three-legged  
8 milking stools - this is biological diversity the way  
9 we traditionally viewed it; if you lost one species,  
10 the stool would tip over. And these three legs on the  
11 stool are soil fertility, biodiversity and genetic  
12 diversity.

13 But we have found that the system has  
14 built into it a great deal of redundancy in processes  
15 and systems, so rather than a three-legged milking  
16 stool we really have a six-legged milking stool.

17 So we can remove one piece, we can lose a  
18 piece out here and the stool won't fall over, but if we  
19 lose two pieces, two legs, we have to be very careful  
20 where that second leg is because if both of them are  
21 lost here, then we have disrupted the system  
22 drastically.

23 But if we lose one here and lose one  
24 here, that is probably no big deal, we can probably  
25 lose a third one. The point is we don't know what

1 we're losing or where, that's the caution.

2 And ultimately in forest management - and  
3 forests will be managed and they should be - we need to  
4 look at the system and ask ourselves some other  
5 questions. If we know what the natural stresses on the  
6 system are, let's say, high elevation, northern  
7 latitude, short growing season, extreme temperatures,  
8 whatever, if we can measure this, then we know on a  
9 scale of zero to a hundred per cent where along this  
10 line that the stress limits of that system are, and  
11 within the limits of its natural stress all systems are  
12 productive, but they are not all as resilient as other  
13 systems.

14 Our high elevation forests are not as  
15 resilient as the low elevation forests. The low  
16 elevation forests have almost zero by comparison to  
17 natural stress. So our range of management stress can  
18 be much higher and not lose a system's ability to have  
19 sustainable processes.

20 But the higher the natural stress on the  
21 system is, the lower our management stress must be in  
22 order to maintain the system within its limits of  
23 resiliency, its ability to bounce back.

24 And we do not look at the systems this  
25 way when we manage yet. I think we're moving in that

1 direction, but this is the direction that ultimately we  
2 have to go, because what we need to maintain, to my  
3 mind, in sustainability is the ability of the system to  
4 adapt to change, which is an ongoing process; because  
5 if we don't, we won't be the losers, but the  
6 generations of the future will, and that to me is the  
7 crux of the issue.

8 MR. LINDGREN: And, Madam Chair, we will  
9 pick up on some of the implications of what Mr. Maser  
10 has described in further portions of the evidence.

11 Q. If I could, Mr. Maser, I would like  
12 to ask you to turn to page 3 of the witness statement.

13 MS. CRONK: Excuse me, Madam Chair. Are  
14 the flip charts going to be marked as exhibits? It's  
15 going to be difficult now to relate the witness'  
16 evidence to the documents that he has just referred to.

17 Was it my friend's intention to mark  
18 them? It would be of great assistance to other  
19 counsel.

20 MR. LINDGREN: Yes, that was my  
21 intention, Madam Chair.

22 MADAM CHAIR: All right, we're going to  
23 give it one exhibit, Mr. Lindgren.

24 MR. LINDGREN: Yes, and I'll mark them as  
25 A, B and C and following.

1 MS. CRONK: Sorry, Madam Chair. Could I  
2 request that there be some description by the witness  
3 of the various flip charts for each of these rather  
4 quickly. The transcript is going to be, in my  
5 respectful submission, incomprehensible on these  
6 documents unless we have some identification.

7 MADAM CHAIR: All right. Could we mark  
8 those. And, Mr. Maser, as we turn the page and mark  
9 each of the pages of the flip chart, could you just  
10 briefly describe what it was--

11 THE WITNESS: Yes.

12 MADAM CHAIR: --so that we give it a  
13 title.

14 THE WITNESS: I would be glad to.

15 MADAM CHAIR: Thank you. And this will  
16 be Exhibit 1672, and A is...?

17 ---EXHIBIT NO. 1672: Series of flip charts introduced  
18 by Chris Maser during evidence  
(Pages A-K).

19 THE WITNESS: A is the traditional way in  
20 the United States that a pulp mill is situated on a  
21 river with its intake and output of water.

22 B is a different way of looking at the  
23 same thing, where the intake is below the output which  
24 causes the mill to pay attention to its effluents.

25 MS. CRONK: Could I ask the witness to

1 slow down just a bit, Madam Chair. Some of us are  
2 trying to get it down.

3 THE WITNESS: Oh, Okay.

4 MADAM CHAIR: Thanks, Mr. Maser.

5 THE WITNESS: That's what happens when I  
6 get excited.

7 MS. CRONK: B...?

8 THE WITNESS: B is a different way of  
9 looking at a pulp mill when the intake pipe is down  
10 river from the effluent pipe and the mill is then  
11 forced to deal with its own effluent rather than  
12 passing it down river.

13 Okay? Well, I'm waiting for you to be  
14 done writing.

15 MS. CRONK: I'm not the relevant person,  
16 sir, the Board is.

17 THE WITNESS: Oh, okay.

18 MADAM CHAIR: We're all set, Mr. Maser,  
19 go ahead with C.

20 THE WITNESS: Sorry about that. C is  
21 looking at the hard limits and the soft limits of a  
22 geographical area in an ecological sense with the soil  
23 as the interactive membrane between the living and  
24 non-living components of that area and the living  
25 components in the centre, which is a way of looking at

1 the system to see where the impacts we are having are  
2 going to be interactive with various components of the  
3 system.

4 And this needs to be looked at in value  
5 neutral. There is no human value imposed on this part  
6 of the system at this point.

7 MADAM CHAIR: Part D?

8 THE WITNESS: D is simply pointing out  
9 that the central part, which is the blue dot that we  
10 inherited at any given point that we happen to approach  
11 the system as human beings, has changed drastically  
12 over time and will continue to change.

13 There is nothing static about ecosystems,  
14 they are dynamic and constantly changing and we must,  
15 therefore, adapt to their change; they will not adapt  
16 to our static view.

17 MADAM CHAIR: And E...?

18 THE WITNESS: E is superimposing a human  
19 value set on the landscape from the perspective of  
20 cyclic thinking or process oriented point of view. This  
21 is value added from a human perspective.

22 F is the same general view, except now  
23 we're looking at a system that is linear, that is  
24 western economic thought and is concerned with products  
25 not processes. And it is very different negotiation of

1 reality with the natural system, and it too is value  
2 added.

3 And neither system is right or wrong,  
4 they're different, and they both have their  
5 compatibilities and they both have their drawbacks, and  
6 we must put them together.

7 G is looking at an area as a cycle and  
8 explaining that a cycle is not necessarily a circle, it  
9 can be any shape and have straight lines. A cycle can  
10 to a point be linear, so that we can fit a plantation  
11 mode into the cycle of sustainable forestry provided it  
12 is done prudently and wisely and we allow the system to  
13 go full cycle on these acres at some point to replenish  
14 themselves.

15 H is simply demonstrating that all  
16 systems organize themselves to a state of self-critical  
17 organization at which point there is a catastrophic  
18 change. There are lots of little incremental changes,  
19 but as the system organizes to a state of critical  
20 change, critical mass, all of sudden there's a  
21 catastrophic change and the system then begins to cycle  
22 in a different way and reorganize differently.

23 We have the opportunity in management, to  
24 some extent, to control how the system cycles by what  
25 we do it, and it would behoove us to maintain the

1        cycling of forested acres in forests if we want forest  
2        products, rather than allowing it to shift to a  
3        grassland land or a shrub field by extracting more than  
4        the system is capable of dealing with.

5                    I simply shows that a system is on a  
6        balance of a peak, it is not a stable entity, it's  
7        always in dynamic tension, and the ball -- or the  
8        system changes and it can go to a lower state of  
9        productivity, a forest to a shrub field, for example.  
10       This can happen without human intervention, it often  
11       does, with fire, or it can happen with management, but  
12       given time, since what we're doing is taking something  
13       away in a sense, if we give the system the opportunity  
14       to heal itself, it can go back and approximate its  
15       beginning, it can complete that cycle and be forest  
16       again.

17                   On the other hand, if we remove too much  
18       or have too great an impact, we have the option of  
19       shifting it to a shrub field or, in our case, a  
20       grassland to a desert so that it may not, within any  
21       human frame of reference, be able to go back to what it  
22       was.

23                   And we have found that any time the  
24       system goes down, it spirals downward in productivity,  
25       the ability for the system to maintain its net primary

1 production goes down. So we have lost, from our point  
2 of view, some productivity of the system; from the  
3 system's point of view, it makes no difference. The  
4 point here is, we need the system a lot worse than it  
5 needs us.

6 J is simply pointing out that we have  
7 greater impact on an ecological system by the  
8 substances, practices or technology we introduce to the  
9 system that are foreign to its ability to cope than we  
10 do by actually taking a piece away from it because of  
11 the built-in ecological redundancy with which the  
12 system has evolved to withstand the shocks of these  
13 changes.

14 This is the resiliency. We interrupt the  
15 resilience of the system with introductions and to a  
16 far greater extent than we do with withdrawals until,  
17 as in the tropics, we're beginning to take away more  
18 than half of the species.

19 When you remove a species from a system,  
20 you don't just remove the species, you remove the  
21 processes that that species was part of and every time  
22 you remove a process, the system shifts a little bit,  
23 even with redundancy, to make that up. If we remove  
24 enough of the redundancy, you can cause the system to  
25 collapse.

1 K is simply looking at the system from a  
2 point of natural stress versus management stress and  
3 how do we balance the two so we can have a forest and  
4 an industry on a sustainable basis.

5 MR. LINDGREN: Thank you, Mr. Maser.

6 Q. Now, a few moments ago you were  
7 discussing the European utilitarian view of the forest  
8 and we find the discussion of that issue at page 3 of  
9 your witness statement.

10 Can you advise me as to whether or not,  
11 in your opinion, whether or not that paradigm is still  
12 prevalent today?

13 A. Yes, it is.

14 Q. Now, as you may know --

15 A. It is in fact changing in Europe, in  
16 Germany faster today than it is in the U.S. even.

17 Q. As you may know, the stated purpose  
18 of the MNR's timber management undertaking is to  
19 provide a continuous and predictable supply of wood for  
20 Ontario's forest products industry.

21 Does that, in your view, reflect that  
22 utilitarian view?

23 A. Yes. In fact to me it is not even  
24 realistic, regardless of where it is, because when we  
25 look at forests as plantations or farms or we're

1 growing trees as a crop, every farmer faces the  
2 vagaries of the climate and weather on an annual basis  
3 and, to my knowledge - in fact, I find it rather  
4 curious that there is any industry in the world that  
5 deals with "renewal natural resources" that doesn't  
6 want to risk the same type of things that every farmer  
7 has to risk.

8           There are no independent variables in the  
9 world and we tend to look at independent variables, and  
10 we can isolate variables such as tree growth if we put  
11 on blinders to the rest of the system and look in a  
12 very short time, but if you look over time there are no  
13 variables. Soil fertility changes, we are altering the  
14 quality of the air which has an impact on the forest.

15           So it seems to me that since the system  
16 is changing it is incumbent on the human being to adapt  
17 to the system, rather than trying to force the system  
18 to adapt to our desires because, in the long run, that  
19 has never proven to work anywhere in history in the  
20 world and I think it's time that we begin to understand  
21 that.

22           Q. Now, throughout your witness  
23 statement you have sometimes used the term industrial  
24 economics.

25           A. Mm-hmm.

1                   Q. Does the provision of a continuous  
2 and predictable supply of wood for Ontario's forest  
3 products industry represent industrial economics in  
4 your view?

5                   A. If you look at it in the straight  
6 linear sense, yes, but it is not a sustainable  
7 economic.

8                   In the United States our industries are  
9 in trouble for a number of reasons - not all because of  
10 the spotted owl, by any means - one is, the forests  
11 have been grossly over cut, because to maintain a  
12 sustained yield means a sustained cut, because you're  
13 cutting and you're not growing it as fast, it is not --  
14 you can cut a lot faster than you can grow, and the  
15 other thing is, it's standing there, that is a much  
16 greater certainty than growing an acre of forest.

17                  Nobody can guarantee me that they can  
18 grow an acre of forest 120 to 200 years because we  
19 don't control insects, we don't control fire. As we  
20 see we're altering the climate, but we can guarantee  
21 that we can cut it down. That's the only guarantee  
22 that I know of. I'm not making a value judgment,  
23 that's simply the way the world stacks up.

24                  Looking at it from an economic view then,  
25 sustainable -- economic sustainability depends on the

1 ecological sustainability of the system, and that has  
2 limits on it, which means that sometimes you can take  
3 more and sometimes a little less, but that must be  
4 balanced with whatever the forest is capable of  
5 producing, and that's not a question we ask.

6 Q. Do you have any comments or views on  
7 the distinction between timber management and forest  
8 management?

9 A. Yes. Timber management is tree  
10 management; forest management takes everything into  
11 account, including soil fertility, the mycorrhizal  
12 component, the processes belowground and human values  
13 other than products.

14 Forest management is learning to  
15 understand the whole system and how do we sustain its  
16 ability to adapt to a changing climate, not just today  
17 but in perpetuity for the future, so long as human  
18 beings are able to inhabit this planet. That's forest  
19 management.

20 I don't know of that being done anywhere  
21 in the world, in the mechanized world. It isn't done  
22 in the United States, it's not done in Europe.

23 They used to say that sustained forestry  
24 or sustained yield was selective logging, but in Norway  
25 within the last few years they went to clearcutting

1 because of the drastic decline of production -- of wood  
2 fiber. We had a Norwegian scientist with us for a  
3 couple of years at Oregon State in the forestry  
4 sciences lab when I was working there, and he was  
5 concerned that in Norway too they had had, I don't know  
6 how many, centuries of selected harvest but ultimately  
7 they had exhausted the soil, and so when the yield  
8 went -- when the decline came in, they went to  
9 clearcutting and they lost a whole softwood forest.

10 What happened was it went to hardwoods,  
11 which was the best thing that could happen. Hardwoods  
12 revitalize, that's nature's -- like, we have alternate  
13 cropping in growing corn, this crop rotation, that's  
14 nature crop rotation in essence.

15 They will get their softwoods back, but  
16 it will be a while. And so that is part of the forest  
17 cycle also and that must be taken into account.

18 Another way of looking at it is when we  
19 clearcut in the Pacific northwest, for example, there's  
20 a shrub that comes in called ceanothus velutinus  
21 (please don't ask me to spell that).

22 Q. I think the court reporter might, but  
23 go ahead.

24 A. I'll take a whirl at it a little  
25 later then.

1                   It comes in following fire, like  
2 broadcast burning after cutting. It also has  
3 nitrogen-fixing nodules on its roots and it happens to  
4 be able to maintain four or five species of mycorrhizal  
5 fungi that are compatible with Douglas-fir on site, so  
6 that when the first seedlings are planted there is a  
7 ready inoculum there of site-adapted mycorrhizae.

8                   We herbicided that for years, we still do  
9 in some places because we're only focussed on the  
10 trees, but as we begin to understand this - and those  
11 areas that have it, they're now beginning to manage for  
12 interplanting trees, they're maintaining a certain  
13 level of this shrub because it does something very  
14 beneficial in preparing the site for the next forest,  
15 the next stand of trees. That is forest management.

16                  Timber management would herbicide that  
17 because they see it as competitive with trees, with  
18 wood fiber production. Timber management is wood fiber  
19 management, as I have seen it practised.

20                  Q. On this point I would like to refer  
21 you to a statement that you make on page 4 of your  
22 witness statement and this is towards the top of the  
23 page in the first full paragraph.

24                  A. Mm-hmm.

25                  Q. And the second line of that first

1 full paragraph indicates that:

2 "The practice of forestry initially is  
3 timber management, that ultimately  
4 becomes regulated plantation management  
5 based on economic concepts that have  
6 nothing whatsoever to do with ecology and  
7 the ecological sustainability of  
8 forestry."

9 A. Mm-hmm.

10 Q. Can I ask you to explain what you  
11 mean by that, and perhaps you can start by indicating  
12 what you mean by plantation management?

13 A. Plantation management is planting  
14 trees in rows to maximize the product, to maximize the  
15 yield of wood fiber while minimizing the cost of  
16 achieving it. And again, there's nothing wrong with  
17 that per se, it's no different than planting corn, it's  
18 an agricultural mode of operation, but that is not  
19 forest management because forests are built on the  
20 accrual of biological diversity, diversity of  
21 processes, diversity of things like large trees, snags,  
22 logs, things that recycle and a forest becomes complex  
23 and it becomes self-regulating.

24 As I was saying here before, it becomes  
25 self-organizing to some point. What we're doing in

1 this case is straightening out the cycle. The idea is  
2 that we can cut plant, cut plant, cut plant ad  
3 infinitum, never lose the yield and never have to allow  
4 the system to go full cycle. That is what -- we are  
5 trying to constrain the ecological system rather than  
6 adapting to it, and I don't know of anywhere in the  
7 world that has worked for very long.

8 In fact there is a book by John Perlin,  
9 which I think I have mentioned, that traces back  
10 deforestation in the world 4,700 years to Mesopotamia  
11 and shows that none of these have succeeded over time.  
12 In fact, there are places in Europe where the land in  
13 ancient history used to be a seaport and today is 13  
14 miles inland because deforestation washed out all of  
15 the top soil and it spilled land out into the ocean, so  
16 now some of these port cities are no longer port  
17 cities.

18 We have the capacity of doing the same  
19 thing if we do not heed the regulations nature gives us  
20 which are unyielding. We must yield; nature will not.

21 MR. LINDGREN: Madam Chair, were you  
22 planning to take a lunch break at this time?

23 MADAM CHAIR: We certainly are, Mr.  
24 Lindgren. We will be back at 1:30, Mr. Maser.

25 THE WITNESS: Thank you.

1 MADAM CHAIR: Thank you.

2 ---Luncheon recess taken at 12:00 p.m.

3 ---On resuming at 1:35 p.m.

4 MADAM CHAIR: Please be seated.

5 Mr. Lindgren, I forgot to make something  
6 an exhibit this morning. Can we add --

7 MR. LINDGREN: Certainly.

8 MADAM CHAIR: These are the Affidavits of  
9 Service for the hearings, the satellite hearings we  
10 were on last fall by Tracy Tieman dated December 14th  
11 in relation to the mail notices for the Timmins  
12 satellite hearing.

13 MS. BLASTORAH: I think there are  
14 actually some for other than Timmins, Mrs. Koven. As  
15 you're aware, that was when Ms. Tieman was away on her  
16 honeymoon. I think there were some for Espanola and  
17 others as well.

18 MADAM CHAIR: Yes, let's go through --  
19 this is the entire package for all the satellite  
20 hearings?

21 MS. BLASTORAH: The Affidavits that were  
22 outstanding. We did file some as we went along.

23 MADAM CHAIR: Yes.

24 MS. BLASTORAH: And the remaining ones  
25 were to be filed, as per my discussion with Mr. Pascoe,

1 at the time upon her return.

2 MADAM CHAIR: All right. Well, I just  
3 have a notice here or note about the Timmins hearing,  
4 so when Mr. Pascoe --

5 MS. BLASTORAH: I think it should  
6 indicate on the Affidavit, but perhaps we could sort it  
7 out at the break.

8 MADAM CHAIR: Yes. This Affidavit only  
9 refers to Timmins.

10 MS. BLASTORAH: I will sort it out with  
11 Mr. Pascoe on the break.

12 MADAM CHAIR: Let's give it an exhibit  
13 number, 1673. Thank you.

14 ---EXHIBIT NO. 1673: Affidavit of Service re:  
15 satellite hearings.

16 MADAM CHAIR: Go ahead, Mr. Lindgren.

17 MR. LINDGREN: Thank you, Madam Chair.

18 Q. Mr. Maser, earlier in this hearing  
19 the Board has heard evidence from the MNR that the aim  
20 of the MNR is to transform the natural forest into the  
21 normal or fully regulated forest containing balanced  
22 age-classes and commercially desirable species.

23 I have two questions for you about that  
24 approach. First of all, in your opinion, is it  
25 ecologically necessary to bring the natural forest into

1       this so-called managed state; and, secondly, having  
2       regard to the set of factors that you have set out on  
3       page 5 regarding nature's design versus man's design,  
4       do you have any concerns about an approach that would  
5       attempt to bring the natural forest into a managed  
6       state?

7                   A. Your first question was, is it  
8       ecologically necessary?

9                   Q. That's correct.

10                  A. No, it is not. It might be  
11       economically desirable, but it's not ecologically  
12       necessary.

13                  As far as concerns, it's unwise, let me  
14       put it that way, because what we're doing is what I  
15       talked about this morning, we're introducing a strategy  
16       into the system that nature is not designed to cope  
17       with, it has not evolved ecologically.

18                  If we, for example, try to make the  
19       unpredictable -- try to entrain the forest, like a  
20       stream, if you've got a stream that has meanders and  
21       you cut off the section here and you straighten it out  
22       in a channel like the U.S. Corps of Engineers has done  
23       all over the U.S. and then you cut off a piece here and  
24       you straighten it out and you maintain an area of  
25       "natural" inbetween, ultimately you destroy the whole

1        thing, because any system -- any ecological system  
2        dissipates energy - we call it the dissipated system or  
3        dissipated structure - and when you entrain something,  
4        when you straighten it out, it's like putting it in a  
5        straight jacket, it's got no way to dissipate a lot of  
6        this energy.

7                    In streams, they destroy their banks and  
8        the channel ultimately; in forests, you end up shifting  
9        it to a direction you don't want it to go in  
10       necessarily if what you would like is to have  
11       sustainable timber production.

12                   I found it interesting in the timber  
13       industry in the United States, for example, that they  
14       talk about old growth being overmature and that we've  
15       got to regulate the forest and get them into young  
16       stands but, at the same time, they covet the old growth  
17       as the highest economic value. Those things to me seem  
18       to be incongruous.

19                   The other thing that occurs to me,  
20       looking at it again from a human point of view as well  
21       as ecological, if the system has produced something  
22       that we like, something that is a benefit to us, to  
23       alter the system to produce something else or to take a  
24       chance on shifting the system's ability to function to  
25       me does not make sense, it's like saying if something

1 works, don't fix it.

2 If you take the second part in looking at  
3 landscapes, one of the arguments that has come up in  
4 the court in the United States over and over and over  
5 again - the courts I've sat in on - is just a few acres  
6 of old growth and it's falling apart, it's overmature,  
7 whatever, and can't we just cut this. You can, but if  
8 you do not look at the watershed or water catchment, if  
9 you do not look at the landscape as a whole, we're  
10 treating this in bits and pieces out of context of the  
11 whole, and the challenge with that is that we end up  
12 not understanding what we're doing. I can give you an  
13 example.

14 A few years ago a wildlife biologist came  
15 to me and he was very upset that the forest supervisor  
16 wanted to cut one acre -- it was one mile of stream  
17 side old growth forest, and he said: But there's  
18 almost none left. Well, they couldn't see that because  
19 they were just looking at a small unit at a time, which  
20 is no different than a big unit, you're still not  
21 looking at it in the context of the landscape.

22 And so I had him draw up the stream units  
23 and colour code them, then I had him draw up all the  
24 acres along the streams that had been impacted, and  
25 what it turned out, when the forester saw the landscape

1 in context with the unit, they were going to impact one  
2 tenth of what was left in tact in that area and they  
3 eliminated the sale, they let it go, they didn't sell  
4 it, because now he had a different view, he had a view  
5 of this in the context of.

6 And the landscape is not just space, we  
7 have to look at these things in time because it's a  
8 dynamic dance between space and time in ecosystems,  
9 it's not static, you cannot put a fence around it and  
10 say it's going to stay here, which is what we try to do  
11 in management with all kinds of things, including farm  
12 fields.

13 In dealing with diversity --

14 Q. And you're referring to Item No. 3?

15 A. Item No. 3.

16 Q. On page 5.

17 A. Right. I appreciate that, I will add  
18 the numbers.

19 Diversity is becoming more important but  
20 we need to define which diversity and in this case the  
21 diversity which is showing up as the most important is  
22 genetic diversity in the face of global warming,  
23 because genetic diversity is frequently a secret  
24 extinction that we don't know about.

25 The argument has been in the States, for

1       example: Well, if you have one parent of Douglas-fir -  
2       this is the pure geneticist's argument - if we have one  
3       set of Douglas-fir, that's all we need, we can populate  
4       the west with this parent stock. You can, but it  
5       probably won't last because the flip side of it is that  
6       the mycorrhizal fungi and the other symbionts in the  
7       soil which interact with the fir's roots, very often  
8       we're beginning to find are not only site-adapted,  
9       we're beginning to think there's genetic compatibility  
10      that has evolved between the above and belowground part  
11      of that system. And so if we ignore that, then what  
12      happens is that we lose these genetic combinations.

13               And that type of diversity in the face of  
14      changes that we have no way to predict, we've got no  
15      idea what's going to happen are critical. They're the  
16      insurance, they are the -- it's like buying insurance  
17      for the forests of the future, it gives us the best  
18      chance of having a resilient forest.

19               So to me it is unwise to eliminate that  
20      when we have absolutely no idea what we're doing or  
21      what the consequences are going to be, and we won't  
22      have to pay for the consequences but maybe your kids or  
23      the kids after, some generation will pick up the bill.

24               And again, this gets back to what I would  
25      call the invisible present; we make a decision today

1 that has invisible cumulative effects into the future  
2 which we can't measure, and so it seemed to me the  
3 prudent thing to do is not do this over entire  
4 landscapes. I'm not saying we shouldn't experiment  
5 with it, but do it cautiously.

6 No. 4. As I said this morning, we deal  
7 with products not with the processes, and if we focus  
8 only on the products and we ignore the processes we end  
9 up losing the products because we destroy the systems  
10 that produce the products.

11 In Europe, for example, they have more  
12 nitrogen in the soil than they've had historically but  
13 the trees don't get it in some of the plantations  
14 because the mycorrhizal component, even if it is still  
15 there - and it is greatly depocreate now because of the  
16 acidity of the soil - the nitrogen translocation part  
17 of that fungal relationship evolved a nitrogen  
18 deficient systems, and so it took nitrogen out of the  
19 soil and moved it into the tree, there was also  
20 nitrogen-fixation going on inside the fungus.

21 Well now with more nitrogen than there  
22 was historically there, the fungus has shut down. It  
23 isn't that it isn't there, it isn't functioning the way  
24 it used to function because something has been  
25 introduced in a way, nitrogen, that the system did not

1        evolve to deal with it, so it altered the function of  
2        the fungi. These are the types of things that we need  
3        to be cognizant of.

4                    5. As I pointed out this morning, the  
5        ecosystem is neutral, there are no value judgments in  
6        this. When we impose a value judgment we now have have  
7        no chance of seeing the system as it really functions,  
8        we see only the product or the end point that we would  
9        like to have. We need to learn to look at the system  
10       and say: What is necessary to keep this system  
11       healthy, and then on top of that, when the necessities  
12       of the system are taken care of, how much can we remove  
13       for our use without impairing the system's ability to  
14       function. That is a fair question, but I think we have  
15       to ask that question because population pressure is  
16       going to put more and more stress on these systems.  
17       And as we change the climate, and as air pollution  
18       takes over, we're having an impact on these systems and  
19       we're altering the variables across the board and we  
20       need to be aware of that.

21                   6. Nature designed the systems to be  
22        flexible and timeless - this is the thing - and it's a  
23        continuum, it's an ever changing thing. We view the  
24        world, I think, in a product mode or linear mode.

25                   We initially viewed it as a film loop,

1 but we saw a frame in that film loop we really liked so  
2 we cut it out, we tried to save it in a scrapbook where  
3 we're going to keep it the same forever.

4 At that point we've destroyed the film,  
5 we've made a film strip and, in this sense, we've  
6 altered the system again. And it isn't that we  
7 shouldn't do anything out there, the challenge we face  
8 is bringing our thinking in line with the way the  
9 system has been designed to function.

10 In fact, if we could do that, if we were  
11 to be open minded and have a beginner's mind, we'd have  
12 a lot more flexibility to manage the system than we do  
13 if we do it with these narrow constraints that we set  
14 for ourselves, because we actually become trapped in  
15 our constraints by law.

16 An example in the United States is, we  
17 have a law that says: You must have all acres  
18 reforested within five years in the west. You cannot  
19 log what you cannot reforest in five years.

20 In my opinion that's a dumb law. It was  
21 done because originally the timber companies were not  
22 reforesting, but what it means is there are a lot of  
23 acres that you couldn't log because they won't reforest  
24 in five years.

25 Now, having something in a shrub field

1 for 20 years or so might be very good for deer  
2 management or something else, it doesn't have to be a  
3 forest in five years, but we've spent an inordinate  
4 amount of money trying to reforest acres that are not  
5 ready to reforest and what has happened is they have  
6 justified cutting them on the basis of the assumption  
7 that they could be reforested, when ecologically we can  
8 look at them and know better, that they won't be.

9 So any time there's a blanket law or  
10 statement or concept like that, I think we put  
11 ourselves in a straight jacket and, to me, that is  
12 neither necessary nor wise. After all, the ecological  
13 system is really quite forgiving, provided we have the  
14 humility to learn from it and adapt with it.

15 Nature designed the forest of long-term  
16 trends and we're designing regulated economic  
17 short-term absolutes in plantations, that's because we  
18 tend to look at the profit margin rather than the  
19 processes of how the system functions.

20 Again, when you focus only on the product  
21 and you look at it from an economic view it says that  
22 anything that's left out there is an economic waste.  
23 And the way the Europeans envisioned it, the gentleman  
24 who came up with the rotation concept is, once the  
25 trees have gone beyond the maximum growth and the yield

1 slows down then they're carrying the investment further  
2 than they need to and they need to cut it so they can  
3 plant another forest.

4 Well, it doesn't work quite that way  
5 because Douglas-fir, for example, goes s-l-u-u-u-r-p  
6 to the nutrients as long as it's growing very fast.  
7 When the tree slows down is when it begins to have an  
8 excess and it puts things back into the system, but  
9 that's the very time that we cut it, and then we put in  
10 another young crop that were sucking those nutrients  
11 out very rapidly; we take out the organic material  
12 faster than it can be replaced or worked into the soil.

13 And the forest and the ecosystem changes  
14 over time and we have got to define these time scales,  
15 which I don't see anywhere, not just here but in the  
16 States or anywhere else.

17 The systems that we deal with have  
18 evolved over a very long period. And, for example,  
19 Douglas-fir has been the dominant in the forest for a  
20 short period, but that's 10,500 years. So in the west  
21 coast we're dealing with a very dynamic forest of which  
22 we really know very little.

23 We have to be cognizant of the time  
24 scales and we have to plan the present in terms of the  
25 future and project it out in a way to understand that

1 the longer you can look at a trend, the better chance  
2 you have of having some predictability in general of  
3 where this thing is going, because if you look at it in  
4 a very short piece that's like having a circle and  
5 you're looking at this much of it and if that's all you  
6 ever see, you can't tell what geometric shape that is,  
7 but if you look at this and you see it start to curve,,  
8 well now, you increase some of the possibilities.

9 If you looked at more of it you can see  
10 more of the possibilities, so you can get some idea of  
11 the trajectory of the system, but we're only looking at  
12 this much and then we're predicting everything else on  
13 this very short blink of an eye. That to me is not  
14 ecologically realistic.

15 8. Forests are designed to be  
16 self-sustaining, self-repairing. That again is the  
17 idea of the self-organizing system. It will take care  
18 of itself and it will change on some pattern, but it  
19 takes care of itself; just like my leg heals, you can't  
20 do it for me.

21 In trying to fix the system with  
22 herbicides, pesticides, fertilizer, whatever is used  
23 wherever it's used, that's a quick fix. We are  
24 impatient with the time scale that the ecosystem has  
25 set up. - Now, we're back to time, we're stuck in our

1 time constraints. We invented the time constraints,  
2 and now we have become a prisoner of the time  
3 constraints.

4 In 1984 I took part -- I was part of the  
5 congressional committee framing the 1985 farm bill for  
6 the U.S. government, and the thing that stunned me,  
7 because I hadn't thought about it, was that soil  
8 erosion is no longer a No. 1 agricultural problem in  
9 the United States, it's pollution of the groundwater  
10 from fertilizers, from chemicals, and they didn't even  
11 take into account herbicides or denticides, fungicides,  
12 pesticides in general, but there was something like, I  
13 don't know, a hundred chemicals or so that -- elements,  
14 compounds that were in the groundwater that were not  
15 historically there.

16 And so I get -- in terms of the future, I  
17 get concerned when I see these chemicals or compounds  
18 being put in the ecosystem because we don't know what  
19 they do, we don't know the effect they have, and we  
20 don't know the cumulative impact over time, and this is  
21 something that I think we need to be very careful with.

22 The other thing is, if you have a system  
23 that is basically healthy producing things like the  
24 system that we harvested originally, I don't think you  
25 can do things economically much better, but they aren't

1 as fast and I think, when I look at all our  
2 technological gadgetry today, I think we have to ask  
3 ourselves when fast enough is fast enough, because  
4 we're really pushing the system.

5 Nature designed a forest with variable  
6 ages and some of them 500 years or more. We're trying  
7 to regulate the age because we're not looking at the  
8 forest now, we're looking at wood fiber as a product,  
9 and so we want to have something even that is  
10 predictable but, again, farming is not predictable, and  
11 in British Columbia I found that the name tree farm  
12 licence - which is what they call their timber licences  
13 - is very apt, because they're converting forests to  
14 tree farms as fast as they can. And that to me has all  
15 the pitfalls of farming in it.

16 And if we're going to farm a forest, we  
17 must accept the pitfalls of the farming, the same as a  
18 corn farmer accepts the pitfalls of the farming; the  
19 difference is they do it annually, we might do it over  
20 80 or a hundred years, but the principles are the same.

21 Our coniferous forests, not yours up here  
22 perhaps, but our coniferous forests have a greater  
23 variety of species that live longer and have a greater  
24 variety or richer than anywhere else and what we are  
25 doing very often is selecting for one or two species,

1 but this has some dramatic impact on soil, for example,  
2 wildlife habitat, and how the systems function.

3 If we've got three trees - and, again,  
4 I'll pick a cedar - we happen to have western red  
5 cedar, hemlock and Douglas-fir - if they all occurred  
6 mixed on acres the cedar decomposes the slowest. It  
7 can be there for centuries, it's also a fairly basic  
8 wood, so it ameliorates the soil. The hemlock rots the  
9 fastest and is similar in acidity and Douglas- fir is  
10 probably the most acidic and is the second longest to  
11 decompose.

12 Now, if we select one of these trees we  
13 are beginning to alter the functioning of the soil  
14 because we have removed components, we've changed the  
15 basic acidity component, we've changed how things rot,  
16 so what we're doing now is, we're beginning to simplify  
17 the system and we thereby simplify the processes. We  
18 can lose mycorrhizae which are adapted to one species  
19 versus another.

20 If you look at the tree in terms of it's  
21 function as wildlife habitat, Douglas-fir in some  
22 respects is the most usable by non-game wildlife, but  
23 our big cedars get heart rot, there are big butt swells  
24 and they have big hollows that fisher, marten and bear  
25 hibernate in. They can't do that in Douglas-fir.

1                   If you look at the cedar also, the bark  
2 comes off loosely, bats can get under it but birds  
3 can't nest in it, it's not good nesting habitat. And  
4 hemlock is essentially relatively useless as wildlife  
5 habitat in our part of the country.

6                   So if you get rid of all of this other  
7 stuff for one species, you're again simply cutting down  
8 the functional diversity of the forest, and this is all  
9 having a tremendous impact over time and this is thje  
10 invisible present that we do not measure well and do  
11 not see.

12                  Q. Now, during the Panel 6 scoping  
13 session the Board raised the following question, and  
14 that is: Can one still have plantations if you're  
15 attempting to practice ecologically sustainable  
16 forestry?

17                  A. Yes, most definitely. That in a  
18 sense, done with prudence and done with humilit, is  
19 similar to what might come in after fire, the  
20 difference with the plantation, we're ordering it, and  
21 there's nothing wrong with that provided we give the  
22 system a chance to heal itself afterwards. You cannot  
23 have plantation and cut it, plantation and cut it,  
24 plantation and cut it, but you can have one plantation,  
25 maybe two, if you monitor the growth of the net primary

1 production or some other measure and then when it  
2 begins to slow down, simply allow that to go full cycle  
3 so it can repair itself. And in that sense the cyclic  
4 nature of the forest is simply recognizing that we  
5 aren't in control, but the system allows us to  
6 straighten it out in linear thinking for a little while  
7 without destroying it, and then allow it to cycle.

8 MR. MARTEL: Have we got any idea of how  
9 long that is in terms of time, and we can take it to  
10 the old growth forest, depending on the variety, but is  
11 there anyone who has attempted to tabulate what those  
12 rotation periods should really be? I'm not talking  
13 about the cutting rotation periods now, I'm talking  
14 about --

15 THE WITNESS: You're talking about the  
16 old growth recycling.

17 MR. MARTEL: Yes, the whole recycle. Has  
18 that anywhere been -- anyone attempted to try to put  
19 that in some context, species by species?

20 THE WITNESS: No, sir, I don't think so  
21 and I'm not sure you could do it species by species, I  
22 think you have to do it by forest type. But I think  
23 the more productive the system and the more careful we  
24 are to leave some biological capital recycle - which I  
25 think we will come to in a little bit - you can

1       probably have a shorter rotation than you would in a  
2       system which is maybe high elevation or way far north  
3       where the growth rate is very slow, the decomposition  
4       may be very slow so the cycling is very slow, that  
5       might take longer to do, but if we are even more  
6       careful with that, then it wouldn't take as long as it  
7       might otherwise.

8               The systems over time are very resilient,  
9       but in the short time, in the context of what humanity  
10      needs from it, that's where we can do the greatest  
11      damage. And so up front we need to build in a buffer,  
12      and I think in the northwest there have been -- well,  
13      I'm going to get ahead a little bit to try and answer  
14      your question a little bit more clearly.

15             There are two components we have to look  
16      at, it in an old growth forest there has been a  
17      continuity of the soil, regardless of what happened on  
18      stop. See, we tend to manage what we see above ground,  
19      and below ground is what I call our management  
20      unconscious, we don't really deal with that.

21             It's been very difficult to study, soil  
22      scientists are only now beginning to tackle it, but the  
23      build up in the continuity of the old growth forest  
24      going round and round and round in the soil over time  
25      is basically unbroken. If we take care of that soil so

1       that we don't disrupt that cycle too much, we can  
2       probably get by with shorter rotations in the resting  
3       stage, but to do that we have to leave snags and logs  
4       and other things out there which are the carry over  
5       component, which are the biological reinvestment. So  
6       if would front-end load the system some and manage the  
7       inputs, not just the outputs, I don't think we have to  
8       have them for tremendously long periods of time in all  
9       areas, one; and, two, we would space them over the  
10      landscape so they're simply built into the management  
11      plan as an ongoing process, not taken out of the  
12      allowable cut - or whatever you folks call it up here  
13      - and the other thing is, you always then have some  
14      first class quality product that can be harvested at  
15      some point, because you have the old growth not just  
16      the young fast growing trees.

17               I think that with some experimentation  
18      can be computed. One of the things that I think is  
19      very important to do - and your question is an  
20      extremely good one - is to set aside enough, which we  
21      will get into also later, to maintain some of the  
22      blueprint, but in other areas see about creating it,  
23      set up some long-term experiments so that some  
24      generation does get the answers from which they can  
25      make target corrections.

1                   The arguments I have heard for years in  
2   court and out of court have been economically, we can't  
3   afford to save this, it's too valuable. My point is  
4   ecologically we can't afford not to the save it, and  
5   the argument is: Well, you can't prove scientifically  
6   that it's needed, and to me the burden of proof is on  
7   the liquidator because they have, to me, prove that it  
8   isn't needed for the future to have sustainability.

9                   Now, if we don't have the answers now and  
10  we are going to cut it because we don't have the  
11  answers, to me that's a flatly ridiculous argument, but  
12  it is valid we don't have the answers, so how do we get  
13  them. We may not, but my question then becomes: How  
14  could we set up management so some generation can get  
15  them. So that if we do make mistakes, we at least make  
16  wiser mistakes than we might have in the past or that  
17  we might otherwise make and that some generation has  
18  ability or the chance or the option of making some  
19  target corrections.

20                   MR. MARTEL: Well then, with large  
21  clearcuts if we don't know what's going on under the--

22                   THE WITNESS: Right.

23                   MR. MARTEL: --upper layer, as you say,  
24  do we really know the overall effects of massive  
25  clearcuts?

1                   THE WITNESS: No, sir, we don't, because  
2 no one has ever done that and then lived through to see  
3 a complete cycle. We have cut the forests massively,  
4 but no one has lived to see the outcome. And what we  
5 do know from what they have learned in Europe is it  
6 takes about a century many times for the biological --  
7 the cumulative biological effects to show up and then  
8 it's too late. It's sort of like rabies, when you get  
9 the disease, when you get the symptoms, you're already  
10 dead.

11                   And ecologically we're not killing the  
12 system, but we may shift it in a way that it loses a  
13 tremendous amount of productivity over time, and if  
14 population continues to grow, I don't think the future  
15 can afford that.

16                   The only thing - to finish up the thought  
17 for you - the only thing that I know of that we have to  
18 offer the future is options, choices and if we do not,  
19 as part of our management, safeguard those options, if  
20 that is not the final aim of management is to pass  
21 forward the options to the next generation, my feeling  
22 is we have not only been derelict as human beings, but  
23 we have also probably set a course in the ecosystem  
24 that may be very detrimental to them in the future as  
25 the climate and other things become less stable than

1       they are today.

2                   MR. LINDGREN:  Q.  On the issue of  
3       regeneration, Mr. Maser, do you have any views or  
4       preferences concerning artificial regeneration versus  
5       natural regeneration techniques?

6                   A.  I would suggest that natural  
7       regeneration is by far the best because you can in fact  
8       manage a native forest by managing the native gene  
9       pool, and with the impending global warming, having the  
10      greatest genetic resilience gives us and the future the  
11      best insurance policy to have adaptable forests in the  
12      future.

13                   Global warming is going to cause the  
14      forests to have to go through some real gyrations and  
15      shifts, and just because a species is spread across the  
16      landscape doesn't mean that the individuals or the  
17      groups of individuals are uniformly adapted across the  
18      landscape, because they're not.

19                   There's a study come out, I was reading  
20      on the plane, about sugar maple for example, that in  
21      the southern part of its range in the United States it  
22      has one form, it's got fairly thick long leaves, in the  
23      northern part of its distribution the leaves are very  
24      thin, and they come on at tremendous volume at very  
25      little cost to the plant and it does not produce the

1 same amount of sugar. Well, if the global warming  
2 comes on the way it is predicted, then the climates we  
3 have in Texas could end up within a century in North  
4 Dakota and forests simply cannot migrate that fast.

5 So the greater the genetic resilience  
6 built into the species as a whole across its  
7 geographical distribution and maintained the better  
8 chance we will have to do something with it because, we  
9 must remember, we don't know in a forest which species  
10 will be able to adapt and within which species which  
11 individuals.

12 It's no different than a group of people  
13 in the United States. We all look like human beings,  
14 but genetically we are a tremendous mix. And so -- or  
15 you can take it in terms of jobs might be a little bit  
16 better way to look at it. We have a tremendous variety  
17 of services we can perform, but if we start plucking  
18 out services to streamline the human being and to  
19 specialize ourselves and there's sudden change, then we  
20 run into problems if we don't have somebody to perform  
21 that function. Genetics is the same thing, that's the  
22 ultimate functional part of adaptability in the system,  
23 and if we remove too much of that we may find out that  
24 we've removed the wrong pieces.

25 Q. And is that why you prefer natural

1 regeneration over artificial regeneration?

2 A. Yes. That is the best way to  
3 maintain that native adaptable genetic mix.

4 Q. Okay, thank you. I understand that  
5 you would like to show some slides to the Board in  
6 order to explain nature's blueprint for a forest. And  
7 before you do that, I just have one question for you.

8 None of your slides were taken in  
9 Ontario. Can you please indicate whether the  
10 ecological principles and processes depicted in the  
11 slides have any relevance for this jurisdiction?

12 A. The ecological principles and  
13 concepts are applicable throughout the temperate  
14 coniferous forests, whether it's Europe, here or  
15 Sweden, that doesn't make the difference. The species  
16 may be different, they may function a little  
17 differently, but the principles and processes are the  
18 same.

19 When we were working with the mycorrhizal  
20 component, our first paper, study came out in 1978,  
21 since then the same relationships, we've been able to  
22 document it in Argentina, it's been documented in the  
23 Pyrenees on the border between France and Spain, it's  
24 been documented in Germany and they've even found that  
25 that small wallabies, the little kangaroos in Australia

1 perform the same type of function in the Eucalyptus  
2 forests.

3 So we find that again redundancy, that  
4 principles and concepts are very broad, species tend to  
5 be much more limited.

6 Q. okay.

7 MR. LINDGREN: Madam Chair, this is slide  
8 No. 1.

9 THE WITNESS: What I'm going to go  
10 through is basically an old growth forest, and the  
11 reason that I'm going to pick the old growth forest is  
12 that is the stage in our forest that is in the most  
13 limited supply. It's also the area in which we have  
14 the entire genetic code in tact and we have all of the  
15 processes functioning.

16 I'm going to show you our understanding  
17 of how a rotting tree functions above and below ground,  
18 and please keep in mind, this is a very, very  
19 simplistic view because we're just beginning to  
20 understand what we think is going on and we're never  
21 really sure of that.

22 Trees come down in our forest usually one  
23 of two ways. In this case, the tree is blown over by  
24 the wind and got caught; the other way is to die  
25 standing as a snag, in which now the processes begin to

1 change and then it gradually falls.

2 MR. LINDGREN: Q. And we're looking at  
3 slide No. 2 here.

4 A. The point I would like to make with  
5 this is that the trees - I hear the term mature and  
6 overmature, those are economic terms, they have nothing  
7 whatever to do with the life of a tree. Trees  
8 potentially, not factually, but potentially are  
9 immortal because they replace their entire living  
10 tissue every year and their entire immune system.

11 What kills trees is not old age, it's  
12 injuries and disease, injuries allow disease to enter,  
13 which may have happened here for example. Trees become  
14 injured and it might take them a century to die. We  
15 can sometimes determine what has killed them, but we  
16 don't know when they contracted whatever it is and what  
17 caused it.

18 Q. This is No. 3.

19 A. Ultimately the trees come down. Now,  
20 the log on the bottom was a healthy tree that got blown  
21 over by the wind, or at least it wasn't caught, it  
22 wasn't dead and rotting or declining. This was a snag  
23 that got blown down.

24 The obvious thing in this slide is that  
25 the two trees, one lying on top of the other, create

1 vertical diversity, habitat diversity, but that is the  
2 only the beginning and the obvious part.

3 Q. This is No. 4.

4 A. When a tree falls, within that first  
5 year, the bark beetles enter it. This beetle happens  
6 to be an ambrosia beetle, it's so-called because there  
7 are small structures in it called mycangia and those  
8 mycangia carry the spores of fungi in them.

9 Now, this little bark beetle does not  
10 feed in the cambium the way most of the bark beetles  
11 do, the cambium was that living tissue just underneath  
12 the bark. That generally is eaten first because it's  
13 the highest in protein.

14 This beetle is a sapwood feeder, which is  
15 the next most important and nutritious part of the  
16 wood, it is very high in carbohydrates. But this  
17 particular beetle does not even eat the wood, it chews  
18 his galleries in the wood, lays its eggs, and the  
19 adults of the larva feed on the ambrosia fungus that  
20 the beetle carried into the wood that germinates.

21 One thing that we learned in a 200-year  
22 log study that is set up on the H. D. Andrews  
23 experimental forest, is that these beetles when they  
24 enter and they would enter a log that goes about from  
25 that table to this bench, there would be about 4,000

1 pairs get into that log within the first year, they're  
2 very small, but they introduce nitrogen-fixing bacteria  
3 at the same time, which means primary nitrogen-fixation  
4 takes place.

5 What that means is, is that the bacteria  
6 have the capacity to reach up into the atmosphere and  
7 pluck out the nitrogen gas internalize it and change it  
8 to a component that is usable by other organisms.

9 So the beetles not only feed on the  
10 fungus but they also start nitrogen-fixation, start  
11 building up nitrogen in the deadwood.

12 Now, the fungus, if the wood is too dry,  
13 does not fruit well and the beetles starve; if the wood  
14 is too wet, the fungus explodes and the beetles smother  
15 in their own food supply.

16 Q. No. 5.

17 A. The next general group that comes in  
18 are the metallic or flat-headed wood borers. They tend  
19 to be sapwood feeders as a whole, but some actually  
20 feed on flowers, but some feed in cambium and some also  
21 in heart wood. Now, in the wood we have a prey base  
22 built up.

23 Q. No. 6.

24 A. And the third one that comes in is  
25 the red predator group, like the red-bellied checker

1 beetle. It feeds on the eggs and larva of the first  
2 two. So now there is a predator/prey relationship  
3 built up in the system.

4 Q. No. 7.

5 A. As the wood continues to decompose  
6 and get wet the mites enter. This mite is called an  
7 oribatid, it feeds on decaying vegetation, but the  
8 mites do a little bit of everything as a whole. As a  
9 group this one is a specialist on dead vegetation,  
10 there's another group that are predators, there's  
11 another group that grazes on fungi, there's another  
12 group that grazes on the bacteria, there's another  
13 group that eats just the droppings of other animals,  
14 and there's a group that actually eats wood.

15 To inoculate their system with the  
16 appropriate little micro-organisms, the protozoan,  
17 which is a one-celled animal, and the bacteria, they  
18 feed on the droppings of the beetles in their  
19 galleries. That inoculates their system and then the  
20 mites can themselves eat the wood.

21 Q. No. 8.

22 A. Next come small groups of insects  
23 like the springtail. The springtail is so-called  
24 because this little appendage back over here, which is  
25 called the furculum is normally folded up underneath

1 the belly and if you were to touch this insect back  
2 here it depresses that very rapidly and it catapults  
3 the insect forward. A lot of cross-country skiers know  
4 these as snow fleas.

5 This little insect feeds primarily on  
6 either bacteria, it grazes bacteria or it feeds on the  
7 strands, the little gossamer threads of fungi.

8 Q. No. 9.

9 A. Another group that gets in at the  
10 right time is the carpenter ant. Now, this one to us  
11 is a critical species, particularly east of our Cascade  
12 Mountains because the carpenter ant colonies are in  
13 large wood. And this is a log, this has been cut. We  
14 are making the large snags, large logs, they are a  
15 finite resource because we are looking mainly at the  
16 old growth forest. They are renewable, but only if we  
17 regrow the big trees.

18 If we never plan to regrow old growth on  
19 long rotations, the large snags, large stumps and large  
20 logs are gone, period, and that will have a dramatic  
21 impact on the functioning of the forest.

22 But for the moment we'll look at the  
23 carpenter ants and they are called carpenter ants  
24 because they chew out their colonies in the wood but  
25 they do not eat the wood, they spit it out. They live

1 in the logging debris up to a point, but this does not  
2 last in the state very long that is compatible with  
3 carpenter ants, so their main viable colonies are in  
4 the dead parts of live old growth trees.

5           These ants are critical to our forests.  
6 One, they are the main diet of the pileated woodpecker  
7 in our part of the country - they may not be out here -  
8 but the other thing is, the carpenter ant we've  
9 discovered through some of the Forest Service  
10 researchers is one of the main predators of the western  
11 spruce budworm in the west.

12           And the way this works is really rather  
13 intriguing. Carpenter ants have two basic food habits.  
14 There's a group that feeds on the honeydew produced by  
15 aphids, which is the aphid's waste product in essence,  
16 it's the sticky part of the sap, an excess that they  
17 suck out of the plants, and the ants actually herd them  
18 around.

19           They take the aphid eggs in the fall into  
20 their colonies, protect them over winter, and in spring  
21 when they hatch they put the little aphids out on to  
22 spring pasture, as it were, and then herd them the way  
23 we might livestock.

24           The other group of carpenter ants are  
25 predators and scavengers. Now, as we cut the old

1 growth forests and as we change the way it is  
2 structured, we're having an impact on the kinds of  
3 birds that can live in the forest. And we found there  
4 are two groups of predators that help to control the  
5 western spruce budworm - they also do the Douglas-fir  
6 tussock moth, but the budworm is a slightly better  
7 example - that is a group of birds called the feeding  
8 guild that feeds specifically on the larva and the pupa  
9 of the budworm and in carpenter ants.

10 But what the scientists discovered was  
11 they knew the birds were feeding on them, so to find  
12 out the effect, they built big chicken wire cages and  
13 put them over whole live trees, and they found that 80  
14 per cent of the western spruce budworm was still  
15 disappearing. Now, they couldn't figure out why, what  
16 was getting it.

17 So finally after several months of  
18 scratching our heads, we put sticky foot, tangle foot -  
19 it's a sticky substance around the base of the tree to  
20 keep the ants out - a hundred per cent survival where  
21 there were no birds and no ants. Where the birds were  
22 kept out and the ants were allowed in, they could  
23 control roughly 80 per cent of the western spruce  
24 budworm when it's in its normal background levels.

25 Where we put sticky foot around the trees

1       it kept the ants off but the birds were allowed to  
2       enter, they found that there was 80 per cent removal  
3       again. So between the two, the ecosystem is balanced  
4       now with these insect outbreaks, which are a normal  
5       part of the cycle.

6                   The thing that created most of our  
7       outbreaks is fire suppression, which has stressed the  
8       system and the tree competition to the point that we  
9       have a lot of stagnant stands and most of the insect  
10      competitors hit trees we found which are not healthy,  
11      they're not vigorous - that's the word I'm looking for.

12                   So if we lose the habitat for the  
13      carpenter ants, let's say we change the forest for  
14      birds, we still have a component in there which is  
15      helping to control the western spruce budworm, but if  
16      we eliminate this also, we can set our managed stands,  
17      as it were, up for just as munchies for the insects  
18      with no -- there's no habitat diversity to break up the  
19      continuity of the insects, we give them a smorgasbord  
20      and we've removed the basic controls.

21                   So one of the things they did was spray  
22      DDT, the Forest Service did when I was working in  
23      northeastern Oregon, and we looked at bats. I was  
24      concerned about that because DDT is a fat soluble  
25      substance. You see, they didn't want to do this, they

1 wanted to get out the product, so they sprayed the  
2 forest, and we found when we looked at the bats that  
3 the California miotus - I'm not sure it gets up here -  
4 but it had about 14,000 times more DDE in it, which is  
5 the metabolite what DDT breaks down to than the other  
6 species because it feeds on aquatic insects and the  
7 aquatic insects, the midges were concentrating the DDT  
8 in the stream water.

9 We also found that DDT is passed to the  
10 young of the year through the mother's milk. And since  
11 bats hibernate, they absorb the DDT in their fat and it  
12 doesn't kill them initially. This is the invisible  
13 present, but during hibernation they can die because  
14 then they metabolize the fat, and can be a lethal dose.

15 And then we found something very  
16 interesting, the United States no longer allows DDT but  
17 we export it, and we had a bat come up -- one of the  
18 bats we worked with was a migrant coming up from Mexico  
19 and it was contaminated, because we sold it across the  
20 border.

21 This is why I'm saying that what you do  
22 to forests in Ontario, what we do to forests in the  
23 United States today affects everyone.

24 Q. No. 10.

25 A. And then there are organisms like

1 millipedes which feed on decaying vegetation. Now,  
2 this particular millipede is in what is called a  
3 molting chamber and I always think of this when I think  
4 about the struggles we have to change our thinking. an  
5 insect or an arthropod like this one, has a stuff  
6 exterior called an exoskeleton, an outside skeleton,  
7 and it becomes hard and the insect can only grow when  
8 it is soft, and then as that outside skeleton hardens,  
9 the insect can no longer grow. So during the molt  
10 they're very vulnerable, but that's also when they're  
11 doing all the growing they're going to do before that  
12 outside skeleton hardens.

13                   And that is like our thinking. We start  
14 out with new ideas, a new thought process, a new  
15 paradigm in forestry and it's risky, and that's where  
16 the old forestry came from, which today I referred to  
17 as plantation management. It was right in its time and  
18 place, but the thinking has become rigid and it no  
19 longer can absorb new data in here because new data  
20 disturbs the old thought process, the old paradigm. So  
21 this has to be cracked so that new thought processes  
22 and a new paradigm can evolve which better fits the  
23 knowledge we have today, but we must also understand  
24 that that paradigm will grow old and must also be  
25 cracked at some point in the future. This must be an

1 ongoing process.

2 Q. No. 11.

3 A. Then there are the large round-headed  
4 wood borers, this one is called arigaties, it lives in  
5 the heart wood primarily which is not very nutritious,  
6 so the larva take from 3 to 7 years to mature, but they  
7 leave behind a burrow that's about an inch in diameter  
8 and that is secondarily used by salamanders.

9 Q. No. 12.

10 A. And then we have termites. We have  
11 the dampwood termite, and the termite is where the  
12 forest starts to get complicated. When you look at a  
13 termite you see the obvious insect, and this is why I  
14 say over and over and over in science we can only  
15 understand the appearances - and that's all we can  
16 understand in management - because what you see here is  
17 really three organisms in one, each appended on the  
18 other.

19 Termites in the fall gather at the  
20 entrance of their colonies and within about one half  
21 hour before flight time - this is the winged form -  
22 they all mature sexually and they take off on what we  
23 call their nuptial flight. When they select their  
24 mates, they land on the ground and they walk to wood,  
25 usually large logs which are ripe for them to inhabit,

1 and they determine this by the odours given off by the  
2 fungi that are decomposing the wood.

3 Once they have found the wood that is  
4 right for the them, they break off their wings, they go  
5 into the wood and they chew out their nuptial chamber.  
6 From there the female is mated and it starts laying  
7 eggs, and the larva then mature and start chewing up  
8 the colony.

9 The termite has very, very powerful  
10 mandibles or jaws, as you can see up here, and they eat  
11 the wood. The wood that they eat is about 70 per cent  
12 infected with decomposition fungi, so it's soft, but  
13 the termite still cannot digest the wood, it depends  
14 for digestion on a one-celled animal, the protozoan,  
15 that has the appropriate enzyme called cellulase to  
16 digest the cellulose that is in the plant cell walls  
17 that gives them rigidity.

18 Here the challenge is that the protozoan  
19 requires a constant supply of nitrogen in order to be  
20 able to perform its function. Nature has endowed the  
21 termite with the protozoan with the one-celled plant,  
22 the bacterium, which is a nitrogen-fixer. It can take  
23 nitrogen out of the atmosphere.

24 So the termite eats the wood, it passes  
25 to its gut, the protozoan digests the wood, the wood

1       that the termite eats we now know does not have a  
2       constant supply of nitrogen, so the nitrogen-fixing  
3       bacterium must keep that supply constant.

4                   And it's sort of like the burner in a hot  
5       air balloon. When nitrogen is deficient the bacterium  
6       turns on; when it is sufficient, the bacterium turns  
7       off. Between the bacteria and the protozoa is a  
8       fermentation process that produces acidic acid. The  
9       acidic soaks through the wall, the gut wall of the  
10      termite and fuels the termite.

11                   This as an obligatory symbiotic  
12      relationship, it's the proverbial marriage made in  
13      heaven; they have to have each other, if something  
14      happens to the one, it happens to the all. And this is  
15      the way our forest functions, in miniature.

16                   Q. No. 13.

17                   A. Then there are small organisms like  
18      pseudoscorpions that feed on the other small organisms,  
19      this is one of the predators.

20                   Q. No. 14.

21                   A. And finally there is the Pacific  
22      folding-door spider. That and centipedes are the top  
23      of the invertebrate predator line, they have very  
24      strong poison claws.

25                   Q. No. 15.

1                   A. Also in the forest are things called  
2 sowbugs. I put these in because they are very  
3 important as food for the salamanders that we have - I  
4 don't know if you have them here - but they are in the  
5 Mexican mountains also that feed on -- that live in the  
6 food.

7                   Q. No. 16.

8                   A. I'm going to, if you don't mind --  
9 will my carousel work in here, these are all jumbled  
10 up. I'm sorry, they're all mixed up, they're not right  
11 side up. That's upside down and that isn't very  
12 conducive to human --

13                  MR. LINDGREN: Well, we can take a  
14 break --

15                  THE WITNESS: If you don't mind things  
16 being all jumbled around, but I don't know the rest of  
17 it, that's why I brought mine.

18                  MR. LINDGREN: Okay. Perhaps, Madam  
19 Chair, we can take a break for a moment to allow Mr.  
20 Maser to put in his carousel of slides.

21                  MADAM CHAIR: Certainly. Go ahead, Mr.  
22 Maser.

23 ---Short recess

24                  THE WITNESS: We have four salamanders  
25 that are in the family plicadontidea - which means

1 lung-less salamander, they in fact do not have lungs -  
2 that live in the wood. Now, you may not have  
3 salamanders but the principle the salamander  
4 demonstrates is applicable here for other organisms.

5 The salamanders absorb their oxygen  
6 through a moist skin and the large logs under a canopy,  
7 whether it is young forest or an old growth forest,  
8 becomes saturated with water and they hold that water  
9 year round. So this in a sense is an aquatic habitat  
10 for the salamanders.

11 They require that in our part of the  
12 country two times out of the year, once in the spring  
13 when they lay their eggs because even though they are  
14 amphibians they lay very large eggs and they lay them  
15 in the wet wood and the larva goes through its aquatic  
16 stage inside the egg. The second time is during the  
17 drought of the summer when the forest dries up, in fact  
18 it becomes like tinder which is when we have our forest  
19 fires, and the salamanders find refuge in the large  
20 wood.

21 The other thing about the large wood  
22 which you might note in Ontario, as we have in Oregon,  
23 when there is a forest fire the wood that was under the  
24 canopy is wet enough to survive and we have found the  
25 wet wood, still wet after the fire, to be refugia for

1 some of the microorganisms which are needed to  
2 reinoculate the sites. So if these large wet logs are  
3 buried or lying on the surface, when fire goes through  
4 many of them retain the living component inside the  
5 wood and that is very important to reinoculating the  
6 system.

7 Q. No. 17.

8 A. Now, we come to the fungi. Fungi are  
9 exceedingly important in the forest because they  
10 basically drive the system.

11 Q. No. 18.

12 A. Let's go to the wood for a moment.  
13 Residence time on the bottom there means the length of  
14 time that the wood lies on the ground decomposing. In  
15 Oregon that is a very long time on the western slope of  
16 the Cascades where it's wet.

17 We may have a 400 or 500-year-old tree  
18 take five or 600 years to decompose and recycle into  
19 the soil. So if you have, let's say, a 400-year-old  
20 tree that lasts on the ground 400 years, that one plant  
21 is influencing that one site for 800 years. This is a  
22 very long time.

23 Q. What does Class 1, Class 2, Class 3  
24 represent?

25 A. I will come to that in just a second.

1 Q. Okay.

2 A. Wood density here on the side is, as  
3 the wood rots it loses density, that means it becomes  
4 spongy and so it absorbs moisture very readily. Log  
5 class was a physical system of characterizing the  
6 rotting wood that we devised when we first started  
7 studying the large logs to give ourselves a way of  
8 understanding what it was we were talking about.  
9 Ecologically it's probably nonsense, but for us we had  
10 to be able to communicate somehow.

11 A Class 1 log is a tree which has just  
12 blown over, it has the needles, it's got the twigs, the  
13 bark is in tact. A Class 2, the needles and twigs are  
14 gone, the large limbs are there and the bark may be  
15 starting to loosen. Class 3, generally the bark is  
16 gone and the sapwood is being utilized by organisms,  
17 and between Class 3 and Class 4 there is a dramatic  
18 shift and this is one of the more important parts we  
19 discovered.

20 Between Class 3 and 4 the sapwood sloughs  
21 off, it simply fragments and falls off, and what is  
22 left is the heart wood. The heart wood is primarily  
23 lignin and in the lignin is a substance called vanillic  
24 acid; that is absolutely critical to the forest in the  
25 formation of humus, which in turn is critical in the

1 formation of mycorrhizae. This is the longest lasting  
2 component and that's why the large, old growth trees  
3 are important; the larger the tree the greater the mass  
4 of the heart wood.

5 Heart wood in this case would be lying on  
6 the surface, down here it would be buried and slowly  
7 incorporating into the forest floor, but in terms of  
8 nutrient cycling in the system, this is the most  
9 important part of that fallen tree, and we will lose  
10 that as we lose the old growth carry over component  
11 unless we plan at some stage, over the landscape, over  
12 time, to replace it.

13 Q. No. 19.

14 A. We have made a lot of mistakes in  
15 science because we too had linear thinking and blinders  
16 on. I think that is an occupational hazard of western  
17 civilization.

18 We looked at logs and for years we argued  
19 for structural diversity, not understanding functional  
20 diversity. If you look at this, here are some  
21 different types of decomposition. Here are the beetle  
22 galleries. This is white pocket rot, this in our  
23 forest turns out to be absolutely critical because what  
24 it does is separate the annual rings between the spring  
25 wood and the summer wood, and in our forest the western

1 hemlock grows on top of those trees, so does Szitcus  
2 spruce, so does Ingleman spruce and, in Europe, Norway  
3 spruce is adapted to grow on rooting wood.

4 The hemlock root tips go down in the  
5 white pocket rot because they can separate the annual  
6 rings and those roots will grow the entire length of  
7 the tree. Without white pocket rot, our hemlock  
8 seedlings would be hard pressed to survive and grow to  
9 hemlock trees in the native forest because hemlock is  
10 is the climax tree. Douglas-fir for us is a fire  
11 subclimax, and the duff layer underneath the  
12 Douglas-fir becomes so thick that hemlock seedlings  
13 cannot get their root tips down to mineral soil before  
14 summer drought and so there's an extremely high  
15 mortality, except for what we call nurse logs.

16 Q. No. 20.

17 A. The fungi I'm going to talk about are  
18 called ectomycorrhizal fungi. Ecto meaning outside,  
19 myco meaning fungus, rrhiza meaning root. These data  
20 are from the Rocky Mountains in Montana in a dry site  
21 just to demonstrate that 66 per cent of this marriage,  
22 the mycorrhizae is an obligatory symbiotic relationship  
23 between the tips of -- tree roots, the root tips, the  
24 feeder roots and the fungus, they have to have each  
25 other, neither survives without the other.

1                   66 per cent of that marriage takes place  
2                   in humus, 21 per cent in decaying wood specifically,  
3                   there are mycorrhizae that are specifically decaying  
4                   wood specialists, 8 per cent with charcoal. Notice  
5                   that if we get rid of the wood component from the soil  
6                   we remove 95 per cent of the mycorrhizal component with  
7                   root tips.

8                   This is what has happened over much of  
9                   southern Europe. In 1985 I looked at soil pits in the  
10                  Bavarian forest that were five feet deep, they have not  
11                  had wood in their soils for over a century. They have  
12                  removed it all. It's called intensive utilization.

13                  That has had a dramatic impact on the  
14                  health of the belowground system because while the  
15                  elements like phosphorus and potassium and sodium are  
16                  there in abundance, this organism, this marriage  
17                  between the fungus and the tree root; the fungus is the  
18                  uptake mechanism, so without fungus - and you don't  
19                  have the fungus without organic material in the soil -  
20                  without that, the elements may be there in an abundant  
21                  supply but the tree cannot access them.

22                  MR. MARTEL: Well then, full-tree -- what  
23                  happens then in full-tree harvesting where you take  
24                  everything basically?

25                  THE WITNESS: There is a dramatic impact

1 on the nutrient capital that is returned to the soil.  
2 It puts the forest in a deficit budget unnecessarily.

3 The primary nutrients that would go back  
4 into the soil are from the crown and the limbs, not  
5 from the trunk. Taking out the trunk does not have  
6 nearly the ecological impact that taking out the whole  
7 tree does. The other thing is, you're pulling out the  
8 roots too, or are you just cutting it off at the top?

9 MR. MARTEL: We cut off the top.

10 THE WITNESS: Because the root systems  
11 are extremely important also, and in some places they  
12 actually take them out.

13 The impact of whole-tree harvest as we  
14 call it, or full-tree harvest is dramatic. The reason  
15 that the trunks or the stems are important is for the  
16 other part of the system I'm going to, that is a much  
17 slower release of nutrients into the system, but the  
18 crowns and the limbs have, I would say - and this is a  
19 guess off the top of my head - but I would say roughly  
20 80 per cent of the nutrients that are in the tree are  
21 in the limbs and the needles. So if you take that out  
22 too, you have taken out a tremendous amount.

23 Q. We're now looking at No. 21.

24 A. This white thing around the root tip  
25 here is the mycorrhizal fungus, we call it a fungal

1 mantle. This happens to be large-pole pine.

2 Now, you will notice that some of the  
3 root tips are not inoculated, like this one here, you  
4 will notice there is no little white dot at the end,  
5 this one has just been inoculated. These root tips  
6 will not survive unless they are inoculated, they  
7 shrivel.

8 What you don't see here is the billions  
9 of miles of gossamer threads going out into the forest  
10 that I will show you in a moment.

11 This root tip has been inoculated. What  
12 this does is stimulate root tip production and it  
13 protects the root tips from pathogens. The pathogenic  
14 or disease-causing fungi are out here in the soil.  
15 These fungi form a hormonal barrier which is a  
16 no-fungus zone which protects the root tips and,  
17 therefore, prolongs their life. To the tree this is  
18 critical because there's a very high turnover in terms  
19 of energy with the renewal of the root tips every year,  
20 to the extent that the fungus maintains and prolongs  
21 the health and life of the root tips, to that extent  
22 the tree can put on radial growth in wood fiber, it is  
23 not putting all of the energy it would put belowground.  
24 The tree puts a tremendous amount of its energy into  
25 maintaining this belowground system.

1 Now, from here--

2 Q. No. 22.

3 A. --the hyphae or mycenia go out into  
4 the soil and form what we call hyphal mats. And if you  
5 could separate these strands, they're about one cell  
6 thick, there are billions upon billions of miles of  
7 these gossamer threads and they act as an extension of  
8 the tree's root system in the soil.

9 The tree cannot get sufficient water,  
10 phosphorus, nitrogen, et cetera, on its own. We have  
11 been able to keep trees, conifers alive in the  
12 greenhouse under conditions of no stress, but we have  
13 found that the first sign of water stress without  
14 mycorrhizae the tree dies.

15 So this is an extension of the tree's  
16 root system, that is why it is absolutely critical to  
17 the survival of the tree. It takes the nutrients and  
18 moves it into the tree's root tip and it then goes up  
19 into the crown.

20 Q. No. 23.

21 A. What it looks like -- this is a  
22 hyphal mat that picks up the water, phosphorus,  
23 nitrogen and other metabolites, other goodies, moves it  
24 into the feeder hyphae which take it to the roots of  
25 the tree through the root tips and it goes up into the

1 crown.

2 The tree in turn sends down sugars from  
3 photosynthesis that goes out through this fungal system  
4 and feeds the fungus. So like the termite, we have one  
5 organism feeding another organism in a mutualistic  
6 relationship which is obligatory to their survival.

7 Q. No. 24.

8 A. There are two kinds of fungi that do  
9 this. Mushrooms, like this bolitus where the spores  
10 come out through these little pores, and gilled fungi--

11 Q. No. 25.

12 A. --like this one where the spores come  
13 out through the gills.

14 We found some interesting things with  
15 this. In our forests in the northwest the mushroom is  
16 not so important as the truffle - which I will show you  
17 in a moment - because these spores are dispersed by the  
18 wind. The spores come out here and they have to blow  
19 through the forest on the air current. They land on  
20 the forest soil and then they have to be washed in with  
21 rain water, and that means they have to percolate down  
22 through the soil and come in contact with roots that  
23 can be inoculated.

24 You will notice here that there's a large  
25 log and here's a Douglas-fir cone. In our forests and

1 in any area where you have forests that form dense  
2 thickets at some stage, the mushroom does not do so  
3 well in inoculating the forest, because if you go into  
4 these dense stands and you get close to the ground  
5 there is almost no wind. The higher up off the ground  
6 you get, the greater the wind velocity. This is where  
7 deer and elk go for what we call thermal cover, they  
8 get out of the influence of the wind in the interior of  
9 stands.

10 So the mushroom is not very effective  
11 there, it is effective after fires, it is effective in  
12 clearcuts, it is effective in mixed forests like you  
13 might have here in the southern part of the province  
14 and like in New York, but it is not so effective in the  
15 very dense stands, and as you get further north where  
16 it's very dry and/or very cold, a dry cold year will  
17 cause the mushrooms not to fruit, and any mushroom  
18 picker knows that.

19 MR. LINDGREN: Mr. Maser, before we  
20 continue, perhaps this might be an appropriate time for  
21 the afternoon break, Madam Chair.

22 MADAM CHAIR: Are you ready for a break?

23 THE WITNESS: It's a good place to stop,  
24 sure.

25 MADAM CHAIR: All right. The Board will

1 return in 20 minutes. And before we break, I have a  
2 note here from Mr. Pascoe that the Affidavits for  
3 Service from the notices in Exhibit 1673 included  
4 Timmins, Hearst and Geraldton.

5 Thank you.

6 ---Recess taken at 2:40 p.m.

7 ---On resuming at 3:00 p.m

8 MR. LINDGREN: I believe, Madam Chair, we  
9 are looking at photograph 26.

10 THE WITNESS: Just to bring you up to  
11 date, the last pictures we looked at were the  
12 mushrooms. These will be called truffles.

13 The mushrooms are called epigeous fungi,  
14 they fruit above ground, these are hecogeous, heco  
15 meaning they fruit belowground.

16 And you will notice the cracks in the  
17 soil here. That is where the fruiting body is, just  
18 below the surface and that's what they look like. Most  
19 people know about truffles because they are used to  
20 flavour food.

21 MR. LINDGREN: Q. This is No. 27 and  
22 we're now on No. 28.

23 A. Unlike the mushroom the truffle has  
24 no way, no natural dispersal mechanism to get its  
25 spores scattered around. This tough outer coat is

1       impervious to water. This is the spore-bearing tissue  
2       in the centre and actually this is in the soil, so this  
3       should be turned around the other way. This is the  
4       outside of it. The spores are in here.

5               Without having evolved the mechanism of  
6       being eaten by small mammals, large mammals like elk  
7       and deer and bear and insects as well, these fungi can  
8       only get their spores dispersed by rotting, they  
9       disintegrate in place and the spores must wash through  
10      the ground water. That is a very cumbersome system.

11             So the fungi having evolved, co-evolved  
12      with primarily small mammals, things like the southern  
13      red-backed vole which you have in Ontario, the northern  
14      flying squirrel, which you have in Ontario, the deer  
15      mouse or the white-footed mouse which you also have in  
16      Ontario, they feed on the spores and then disperse the  
17      fungi. And I will come back to that.

18             Q. No. 29.

19             A. These fungi come in a variety of  
20      sizes and shapes in terms of their fruiting bodies.

21             Q. No. 30. No. 31.

22             A. The point is, however, that this  
23      whole system is belowground. You saw the mantles  
24      around the root tips, you saw the hyphae go out into  
25      the soil and form the hyphal mats where they pick up

1 the nutrients, move it into the tree's root which is  
2 right here, through the feeder hyphae, up into the tree  
3 and the tree feeds the fungus sugars from  
4 photosynthesis.

5 When the temperature and moisture  
6 conditions are right, a fruiting body is formed totally  
7 belowground. So this whole system is out of site.  
8 That is very important in those areas where there are  
9 either cold snaps, dry snaps, or very dense forests  
10 because this system does not depend on wind or the  
11 above ground weather to be dispersed, it depends on  
12 being eaten by small rodents primarily.

13 Q. No. 31.

14 A. Let's go back to the wood for a  
15 moment. As the wood lies on the ground rotting, the  
16 residence time, it increases in moisture, water. You  
17 will notice this is a live tree right here and by the  
18 time it is all heart wood it is 200 per cent of the  
19 moisture that it was originally. At this point it  
20 remains saturated.

21 This is buried now and beginning to break  
22 down belowground. This is a totally saturated log  
23 which is just heart wood. Under a canopy, be it old  
24 growth or young growth, that remains a water reservoir  
25 throughout the summer, throughout the year.

1 Q. No. 33.

2 A. Here is a round, a wafer we call it,  
3 that we cut out. You will notice the different kinds  
4 of decomposition. So this is functional diversity in  
5 here, these cause the wood to rot differently and this  
6 wet spot is metabolic water, as we call it, it's  
7 produced by the decomposition of the wood through  
8 bacterial action primarily.

9 Q. No. 34.

10 A. This is heart wood of a large tree  
11 that's all that's left of it is totally saturated. I  
12 can take my arm and push it in here almost up to my  
13 elbow it is so smushy, grab a hand-full of wood and  
14 pull it out and squeeze the water out of it. You will  
15 notice that it's dark down here, that is where it has  
16 the greatest saturation, and this was taken I might add  
17 in July on an exceedingly hot year.

18 Now, there are some things I would like  
19 you to notice about this. Notice the slope, how gentle  
20 that slope is, but look at all of the soil and organic  
21 material that is held in place on the upslope side.

22 This on slopes prevents what we call soil  
23 creep, it prevents erosion. When this large woody  
24 material is left in place going along the contour, it  
25 helps hold the soil in place.

1                   If you look at the downslope side, right  
2 here, below the log you will notice there is an open  
3 triangle. This open triangle is the protective  
4 covering that the small mammals have available as  
5 habitat to prevent them from being eaten by owls, and  
6 this is where they travel in their normal activity, and  
7 that is also where they disperse most of the  
8 mycorrhizal spores in their little pooparoonies.

9                   This is the most dynamic portion of the  
10 system right here in terms of nutrient exchange with  
11 wood, and we know virtually nothing about it. There  
12 has been a 200-year long log study instituted in the H.  
13 J. Andrews experimental forest that is now -- this  
14 study was set up for the generations of the future,  
15 starting a few years ago, and it is funded to be  
16 completed 200 years from now so some generation has the  
17 answers we struggle with today.

18                   Q. No. 35.

19                   A. This particular fungus, to show you  
20 how some of these things become adapted, is called  
21 rhizopogon vinicolor - I'm sorry it has no common  
22 name - it is a truffle and it is specifically adapted  
23 to the roots of Douglas-fir, it occurs with no other  
24 tree and it is a rotten wood specialist.

25                   This is very important, because this is a

1 Douglas-fir root and here is the mycorrhizae which is  
2 the marriage between the fungi and the root of the  
3 Douglas-fir forming what we call tuberculite  
4 mycorrhizae with little structures that we call  
5 rhizomorphs.

6 The rhyzomorph you might think of as a  
7 siphon that's very adept at taking water out of wood.  
8 This is a rotten wood specialist. That fungus goes  
9 into the wood with the root tips of the fir and it  
10 extracts the water from that wood reservoir and takes  
11 it into the Douglas-fir.

12 In our forest during the summer that is  
13 important because as the summer drought continues the  
14 mycorrhizae in the root tips that are near the soil  
15 shrivel up and the forests -- our forests shut down. I  
16 don't know when your forests put on most of their --  
17 produce most of their photosynthesis, ours does it  
18 during the winter. So during the summer they close  
19 down, they close the little openings in the leaves, the  
20 stomates to prevent the loss of water, but they  
21 continue to grow where the water is available from the  
22 logs through the fungus.

23 We have also found that seedlings that  
24 are planted in clearcuts that have this associate on  
25 their root tips are twice as drought resistant as those

1 that don't have it. So just because you inoculate  
2 seedlings in a nursery and outplant them doesn't mean  
3 that they're going to survive.

4 We have found whole plantations that are  
5 dead and at first we blamed it on animal damage and we  
6 pulled them up and looked at them and discovered that  
7 the trees were non-mycorrhizal in the sense that the  
8 fungus that was in the nursery was not adapted to the  
9 site.

10 And so just as people think of seed  
11 zones, they know the trees are adapted to, let's say,  
12 certain elevations, we're beginning to understand that  
13 a lot of the fungi are similarly adapted and we're  
14 beginning to think that there is some genetic  
15 compatibility between the site-adapted fungi and the  
16 site-adapted tree. It's much more specific than we  
17 have heretofore thought.

18 Let's go back to the wood for a moment.

19 Q. Sorry, to interrupt. We are now  
20 looking at No. 37.

21 A. Residence time again is the length of  
22 time that the wood is lying on the ground and this is  
23 the curve for nitrogen input into the rotting wood. A  
24 phosphorus curve is somewhat similar. This is an older  
25 slide but the point is still there, it increases in

1        nutrients as it lies on the ground.

2                    The nutrients come in in several ways.

3        In an old growth forest the rain water or the snowmelt  
4        that comes through the canopy brings a lot of nutrients  
5        with it from the lichens that grow in the tree tops.  
6        We call them epiphytes. A lichen is another  
7        mutualistic plant, the fungus forms the body outside  
8        and the colour is given by algae that live inside the  
9        fungus body, together the algae produces the  
10       photosynthesis that feeds the fungus and the fungus  
11       houses the algae.

12                   Some of these algae, the blue-green  
13        algae, can fix nitrogen, and so as they decompose and  
14        break down in the tree tops and water comes through,  
15        there is a nitrogen input into the wood simply by the  
16        water soaking in and the nitrogen then accumulates.

17                   Organisms die in the wood and roots  
18        penetrate the wood in the fungi, and when they die in  
19        the log, whatever elements they have in their bodies  
20        are trapped, and then there's nitrogen-fixation  
21        introduced by the beetles. So this makes an idealic  
22        state.

23                   Q. No. 38.

24                   A. Let's recap for a moment. A big tree  
25        falls over and there's a large log on the ground and,

1 let's say, it's there -- it starts to break down,  
2 within the first year the cambium tends to go very  
3 rapidly, then the sapwood. While the organisms are  
4 decomposing inside, the fungi, the insects are eating  
5 it up, it opens it up with lots of little tunnels and  
6 checks and cracks. This allows the plant and animal  
7 community inside the wood to explode, not only in  
8 numbers but in kinds.

9 Now, we have determined that a tree like  
10 this which is on the ground, when the sapwood is  
11 occupied to its maximum, has twice the living biomass  
12 of cells that the live tree had. So ecologically this  
13 is more alive than the live tree.

14 As it decomposes and the sapwood sloughs  
15 off and becomes heart wood it begins to serve a  
16 different function, it becomes very simple, and the  
17 only things that we know to date that can break down  
18 the lignin and release the vanillic acid which is the  
19 organisms in use as a carbon source or food, are the  
20 fungi and the bacteria.

21 Now, while all of this is going on inside  
22 inside, internal succession if you will, the outside  
23 community is growing up around the log and beginning to  
24 protect it from sunlight and wind and allowing it to  
25 remain -- to retain more of its moisture. So an

1 external succession goes on simultaneously, the forest  
2 grows up and the log sinks into the soil.

3 What that does is take the old part of  
4 the forest, of the old forest in the wood and it  
5 recycles it into the soil to be used by the next  
6 forest. This is biological capital that is being  
7 reinvested. We cannot invest biological capital per se  
8 we cannot -- we can divest it, we cannot invest it, we  
9 can only reinvest it by leaving it out there.

10 If you make an economic reinvestment in  
11 something what you do is make the money first by  
12 selling products or whatever, then you take a portion  
13 of that capital and you put it back into the  
14 maintenance of the business, that's an economic  
15 reinvestment. We cannot do that in a forest because  
16 the forest does not run on money, we cannot fix the  
17 pieces.

18 So biological capital is reinvested by  
19 not harvesting it, by leaving a portion out there to  
20 recycle to maintain the health of the soil.

21 MADAM CHAIR: Excuse me, Mr. Maser.

22 THE WITNESS: Yes?

23 MADAM CHAIR: One question that we put to  
24 your counsel for your consideration during the scoping  
25 session was whether leaving slash on the site

1 substitutes in a way as being a type of biological  
2 reinvestment as opposed to waiting for old trees to  
3 fall down and decompose.

4 THE WITNESS: Right. There are a number  
5 of ways of doing that and slash can do it up to a  
6 point. The fine tops, as we spoke about before, yes,  
7 when they're scattered over the landscape, but if  
8 they're windrowed, if they're piled or put in rows that  
9 is exceedingly detrimental, it does nothing for the all  
10 over area for one thing; and, two, one of the big  
11 problems we're finding is soil compaction and any  
12 unnecessary activity in terms of large equipment that  
13 compacts the soil has a tremendous impact on these  
14 processes belowground and we are only now beginning to  
15 ask those questions.

16 So I would suggest that windrowing is  
17 exceedingly dangerous over time and so is piling  
18 especially windrowing and or piling and burning.

19 Slash in British Columbia is this high, I  
20 mean, you can fall off it and really injure yourself  
21 because they simply cut the forest and left -- I have  
22 never seen anything like it in my life anywhere I have  
23 ever been.

24 Now, you can say that it's not biological  
25 waste, and that's true, but bear in mind that if you

1 plan never to grow these big trees again that is a  
2 one-time shot in the arm for the forest. What do you  
3 do after that? That's is the concern I've got.

4 I'm not concerned with now, leaving slash  
5 is cheap, it costs nothing, but what about the next  
6 rotation and the rotation after that. That's the  
7 critical part.

8 That means we have to actually leave some  
9 biological reinvestment at some cost, no different than  
10 running a mill, no different than maintaining a logging  
11 operation, we must consciously leave some there. That  
12 we are not planning to do that I'm aware of anywhere.  
13 We are starting to do it in the States, but there has  
14 been a tremendous hassle over it and it isn't that  
15 anyone looks at this with malice or looks at it in a  
16 skewed way, it's simply that new ideas take a long time  
17 to catch on and as we learn more, we simply have to  
18 change.

19 Leaving slash, I would say, is good  
20 depending on how it's left and where it's left and that  
21 doesn't mean that you can't have fire breaks in it, it  
22 doesn't mean that you can't do a variety of things. We  
23 actually have some sales in the States these days where  
24 the contractors actually, if they don't have enough  
25 wood along the contour, they are placing the logs. We

1 also have sales which we call shelterwoods. Are you  
2 familiar with that?

3 MADAM CHAIR: Yes.

4 THE WITNESS: In which the overstorey is  
5 not going to be cut, that is the reason that they cut  
6 the initial 80 per cent, the last 20 per cent will not  
7 come back in for a harvest. That is the reinvestment  
8 for the next stand and the stand after that, that's the  
9 carryover. There are a tremendous number of options  
10 available.

11 MADAM CHAIR: Do you have any sense of  
12 the placement of standing timber or the density of it  
13 that makes sense, or is that very dependent on the  
14 site?

15 THE WITNESS: That's dependent on the  
16 site and I would not presume to be the expert here.  
17 From our experience, the way we did this - since you  
18 asked the question, and it's an excellent one - I would  
19 like to get one thing clear.

20 One, I do not view myself as an expert,  
21 least of all in somebody else's country and least of  
22 all in somebody else's backyard. I have found that we  
23 didn't have the data in the United States and we've  
24 studied this for a decade and we still couldn't give  
25 that kind of answer.

1                   So what we did, we got some district  
2           rangers on the acres that they had and we went out and  
3           we looked at clearcuts and we had silviculturalists, we  
4           had pathologists, we had insect people, we had fire  
5           people, we had soil scientists, we had the gamit and we  
6           went out and we looked at clearcuts and we looked at  
7           the specific thing, the amount of dead wood that's left  
8           and the size, and we then discussed what we were  
9           comfortable with based on what we knew, and when we  
10          came to an agreement on that we went to another area  
11          and we looked at distribution of wood, and we did this  
12          for a week and by the end of the week we had the best  
13          management plan I have ever seen.

14                   And I will submit that we will never  
15          manage based on technology or data when it comes to  
16          making decisions, we will always choose human values.  
17          And science and technology will not change the world,  
18          people will, and I think we sell ourselves short.

19                   In the last analysis, I don't care how we  
20          rationalize these things intellectually, if we don't  
21          feel good about it there is something fundamentally  
22          wrong with it.

23                   So we have taken our best data and then  
24          we've put it to the ultimate test for us, how do we  
25          feel about what we've come up with. Then what we've

1 done is design long-term experiments on the public  
2 lands so that some generation can get the answers that  
3 we could only really guess at.

4 This to me is giving a gift or setting up  
5 at least so that some generation has the option of  
6 actually testing the data that we can only surmise  
7 based on all the years that we have looked at it. Does  
8 that get at your question?

9 MADAM CHAIR: Yes, it did. But in the  
10 work you were doing on that management plan, you were  
11 looking at dead wood as opposed to standing timber that  
12 will be part of the succession of --

13 THE WITNESS: We worked backwards then,  
14 what they did, what the rangers then did, we said --

15 MS. CRONK: Sorry, Madam Chair, we can't  
16 hear the witness.

17 THE WITNESS: Oh, I'm sorry. What we did  
18 was then say, this is what we feel comfortable with,  
19 now if we project into the future on future stands,  
20 what do we have to leave out there and what  
21 configuration to accomplish this.

22 And they came up with some very  
23 elaborate, very good plans which they are now testing  
24 in fact. What is the economic cost of doing it this  
25 the way or that way, what are the options of achieving

1 these types of leave areas, what are the ecological  
2 costs of not doing it, and they have designed a number  
3 of experiments which are going to be carried out under  
4 normal management with scientific supervision,  
5 supervision from the scientists, so that in a hundred  
6 years, 150 years somebody has some answers.

7 We are not capable of deriving those  
8 answers today, except the way that I indicated that we  
9 have done it, and I am very comfortable with those  
10 answers.

11 MR. LINDGREN: Q. No. 39.

12 MS. CRONK: Excuse me, Madam Chair. A  
13 few moments ago the witness referred, with his hands,  
14 to the height of slash in British Columbia and he  
15 sort of did give you some evidence about that.

16 I wonder, for the benefit of other  
17 counsel - and I'm sorry to interrupt - and for the  
18 assistance of the Board, so that it's clear as we go  
19 along, that we have the witness indicate the height to  
20 which he was referring. He simply said this high.

21 THE WITNESS: Oh. Can you hear me better  
22 now?

23 MS. CRONK: Yes, thank you very much.

24 THE WITNESS: In British Columbia the  
25 slash is about like this on clearcuts that have been,

1 oh must be about four feet off the ground.

2 MS. CRONK: Thank you.

3 THE WITNESS: Okay. Some of it's deeper.

4 As I said before, our western hemlock evolved to  
5 germinate on dead wood. These are hemlock seedlings  
6 that are less than one year old.

7 They evolved to be able to live without  
8 the mycorrhizal component initially because mycorrhizae  
9 in dead wood is not very -- does not form readily when  
10 it's on a log which is, you know, three feet off the  
11 ground because these were big trees. There's a very  
12 high mortality rate, which is the cost.

13 Now, this is what we call a nurse log  
14 because--

15 Q. No. 40.

16 A. --it is high in moisture, it's high  
17 in nutrients and it's spongy, it's an ideal rooting  
18 medium.

19 These hemlock seedlings do not get this  
20 large however without being inoculated and the  
21 inoculant may come from fungal spores being blown up  
22 with the wind, we find some mushrooms fruiting here,  
23 which are mycorrhizal with the hemlock, but most of it  
24 we find comes from the pooparoonies of the flying  
25 squirrel at night, the chickaree in our part of

1 country - in your part of the country it's the red  
2 squirrel - during the day, and the deer mouse at night  
3 and also the chipmunk, and I don't know which chipmunks  
4 you have here.

5 But the fact is that the small mammals  
6 get up here, and when they leave their little calling  
7 cards they break down and they wash in with the water  
8 and they inoculate the hemlock roots.

9 Q. No. 41.

10 A. These little white spots here are the  
11 inoculated root tips of hemlock. Now, our hemlock is a  
12 weird tree because it didn't read the botany books. It  
13 grows up stumps, it will grow up into an old dead  
14 stump, cross over to a log and grow down the full  
15 length of the log. And so the wood is very important  
16 to it. It grows exceedingly well in mineral soil, but  
17 being the understorey component, the climax species of  
18 the fire-dependent old growth ecosystem, this is the  
19 other way it has evolved to grow.

20 Q. This is No. 42.

21 A. Here is a hemlock tree and here is  
22 its root, like a hand holding on to its nutrient  
23 supply - I pulled the bark off - which is a large snag,  
24 a dead portion. It grew, it germinated on the side of  
25 this dead tree, you can see here in the bark, and its

1 roots grew up and are now extracting nutrients from  
2 that tree.

3 Q. This is No. 42. Madam Chair, the  
4 previously photograph is a new photograph and we'll  
5 undertake to provide copies.

6 A. Oh, I'm sorry. This is my normal  
7 lecture.

8 Q. That's okay.

9 MS. BLASTORAH: Perhaps we could refer to  
10 that as 41A just for the purposes of the record.

11 MR. LINDGREN: Thank you.

12 Q. We are now looking at No. 42.

13 A. This is a Szitcus spruce tree which  
14 germinated on a fallen log when the log was about up to  
15 here, this is where the butt swell starts. The log has  
16 since disappeared and the tree is using up the  
17 nutrients, here are its roots. Now, these roots  
18 originally grew underneath the bark and they grew out  
19 the bottom of the bark as the log was decomposing.  
20 When a log rots out completely, it leaves the tree on  
21 stilts.

22 Q. No. 43.

23 A. And a lot of the Olympic Peninsula is  
24 like this and we found the same thing in higher  
25 elevation in the Swiss Alps and the German Alps along

1 the border where the trees still had enough logs to  
2 grow on.

3 In Alaska and in the muskeg area, these  
4 fallen trees are very important to the germination and  
5 growth of the forest for another reason, there the  
6 seedlings perch on top of the fallen trees to keep out  
7 of the water, and then once they are established, their  
8 roots can grow down. So these large logs form more  
9 than one set of scenarios in the system.

10 Q. No. 44.

11 A. Now, as I said before, we make a lot  
12 of mistakes and we have not had our share of humility  
13 science and this was one of the more dramatic lessons  
14 to me.

15 We discovered a few years ago that inside  
16 the mycorrhizal fungal material were nitrogen-fixing  
17 bacteria. No one had ever seen that before. So we did  
18 what good scientists do, we thought in intellectual  
19 isolation and we successfully killed the whole system  
20 for one year, because we needed we thought a culture in  
21 which we could separate the fungus from the bacterium,  
22 and we did that and we sterilized it and we killed it  
23 successfully.

24 Finally we ended up with a mistake, we  
25 got a contaminated petri dish and this was the result.

1       These little fuzzy things are the fungus and this is  
2       the bacteria colony and, like the termite, the whole  
3       system works beautifully. This fixes a tremendous  
4       amount of nitrogen. And we tested this over and over  
5       with acetyline reduction, which is a technique for  
6       getting at nitrogen-fixation.

7                       This is growing on nitrogen-free medium,  
8       augered medium. Now, when we discovered this we also  
9       realized that the small mammals we had studied for  
10      years fed on the fruiting bodies of the mycorrhizal  
11      fungi, so a logical question: Was do small mammals  
12      send through their system nitrogen-fixing bacteria and  
13      noculate the soil with the spores.

14                     I think I found the only benevolent use  
15      of terror in the world. We wanted to use flying  
16      squirrels but we didn't want to kill them, so we  
17      trapped them alive and we put them in sterile white  
18      cloth sacks and I terrorized them for 30 seconds and we  
19      always had calling cards.

20                     And we take these little calling cards  
21      back to the lab and we inoculated the petri dishes and  
22      this is what we got. This is a nitrogen-fixing  
23      bacterium. Now, if you'll notice it is long ones and  
24      straight ones and short ones and fat ones and curved  
25      ones and skinny ones. Obviously in our thinking that

1 was contaminated, so we threw it out, and we threw it  
2 out trial, after trial, after trial for six months.

3 And then a friend of ours, a Dr. Telac  
4 from New Delhi, India, who is a world class  
5 microbiologist came to the States to study mycorrhizae  
6 because they are replacing rhizobium in the nodules on  
7 soya beans with a bacterium called azosperium and  
8 they're doubling and tripling their crops under  
9 experimental conditions.

10 So in frustration the C.Y. Li who is the  
11 Chinese micobiologist working with us said: Telac, do  
12 you know what this? He said: Oh yes, that's  
13 azosperium. It's highly polymorphic, that means it  
14 comes in many shapes. And we had a pure culture the  
15 first time around, but with our straight line mentality  
16 and our isolated thinking we threw this out.

17 Now, this is from the flying squirrel.  
18 We also got it from a number of other animals. One --  
19 then we tested the deer mouse--

20 Q. This is No. 46.

21 A. --which we in the States had poisoned  
22 at the cost of millions of dollars over the years  
23 because they ate tree seeds in areas of natural  
24 regeneration. But if you'll notice these little green  
25 areas, those are resting spores called endospores,

1       inside spores. This bacterium is a nitrogen-fixer  
2       which is a textbook classic called Clostridium  
3       butyricum. In every textbook that deals with  
4       nitrogen-fixation that I've seen, this organism is  
5       mentioned.

6                    You see, we never asked what the deer  
7       mouse did that might be beneficial to the system and  
8       this is what I said before, in science we must be very  
9       careful and have a great deal of humility because all  
10      we can ever interpret is the appearance and the  
11      appearance was the deer mouse was detrimental to  
12      reforestation, to planting trees.

13                   In fact the surface of our clearcuts in  
14      the summer, particularly if they had been burned, can  
15      reach 160 degrees fahrenheit and these little spores  
16      can withstand those temperatures, so the deer mouse  
17      serves a very important function.

18                   Q. This is No. 47.

19                   A. Now, inside the animals is a pouch  
20      called the cecum, which this will have to represent.  
21      The mouth is up here and it goes from the mouth to the  
22      stomach, to the small intestine, and at the juncture  
23      with the large intestine which becomes the colon and  
24      the rectum is a pouch called the cecum.

25                   And we discovered when we were working

1 with the food habits of the animals that in the flying  
2 squirrel there were yeast propagules - now, yeast is  
3 another kind of fungus - and in the deer mouse there  
4 was so much yeast we couldn't count it, and this is a  
5 drop diluted -- this is a hundred times dilution.

6 What we discovered was there was more  
7 yeast going through the small mammals than we could  
8 find in a given area in the ground of a similar size.  
9 So we wondered what this was all about, and we found  
10 that the nitrogen-fixing bacterium, azosperium, is fed  
11 by the extract of another fungus, that's why in the  
12 contaminated petri dish the fungus was feeding the  
13 bacteria and the bacteria was producing nitrogen which  
14 kept the fungus going.

15 The yeast inside the small mammals lives,  
16 it does not die in going through the cecum, so while it  
17 is circulating in the cecum it's producing nitrogen  
18 which keeps the nitrogen-fixing bacteria, it feeds the  
19 bacteria, the bacteria in turn keeps the mycorrhizal  
20 spores going.

21 So the way this works is, the animal at  
22 the front end is a little pharmacy, it eats the  
23 material, it stores it in the cecum, it concentrates  
24 it, it forms it in fecal pellets and it goes out  
25 through the dispensary and out into the forest soil.

1                   Working with deer mice we found that they  
2                   can hold this material inside their bodies for up to  
3                   one month after their last meal, and a colleague of  
4                   ours at Wake Forest University in Winston, Salem North  
5                   Carolina has been studying the endangered fox squirrel  
6                   that lives in long-leaf pine plantations in forests in  
7                   the south, and he copied what we had done and found  
8                   that the fox squirrel can maintain within itself this  
9                   inoculum for up to 84 days after its last meal.

10                  Now, that's important, because when we  
11                  study the deer mice I did something I promised myself I  
12                  would never do, I spent a winter counting animal poops,  
13                  and I wouldn't do that because that's what the big game  
14                  biologists do and I never really wanted to be a  
15                  biologist. This was much more sophisticated, however.

16                  We found that deer mice give off an  
17                  average of 66 pellets in 24 hours. I mean, that was  
18                  really exciting stuff. And we found that the  
19                  red-backed vole gives off about 300 pellets in 12  
20                  hours, in fact the red-backed vole on the coast in  
21                  Washington - the same species you have here but in the  
22                  State of Washington - is so dependent on the fungi that  
23                  they eat more than their weight every 12 hours or they  
24                  starve to death, of this fungus. It also gives them  
25                  their water supply.

1                   Now, the reason the pellets are important  
2                   because it takes 1 in 10,000 mycorrhizal spores to  
3                   inoculate one root tip of one tree and when the deer  
4                   mice have been eating just the fruiting bodies they  
5                   have between 800 -- 500 and 800,000 spores in each  
6                   pellett, plus nitrogen-fixing bacteria, plus yeast.

7                   The red-backed vole has about 300,000  
8                   spores and one deer, one little round deer pellet has a  
9                   about 2-million. So they are very potent inocula in  
10                  the forest soil.

11                 Q. No. 49.

12                 A. What we did then was take the animal  
13                 droppings from our lab experiments and we got some in  
14                 the field and we macerated them in distilled water and  
15                 we inoculated sterilely-grown seedlings, we used  
16                 Douglas-fir, but it has since been done on large-pole  
17                 pine.

18                 We put inoculum in here, the seedlings --  
19                 there were no nutrients in the tube and what we put in  
20                 was a slurry of mycorrhizal spores, yeast and the  
21                 nitrogen-fixing bacteria. Now, the thing that is  
22                 important with this is we used three genre of fungi,  
23                 two of which no one had ever been able to germinate in  
24                 a laboratory.

25                 When they went through the animal's

1 intestinal tract all three germinated, and so we are  
2 beginning to question whether or not going through a GI  
3 tract of an animal may be necessary to what's called  
4 stratify the spore.

5               Some tree seeds need to be frozen before  
6 they will germinate, they have to go through a cycle.  
7 Do these have to go through heat? One of our  
8 colleagues heated some of them to a critical  
9 temperature very fast and took them away, and lo and  
10 behold, it also germinated.

11              Now, the animal temperature is fairly  
12 high internally and if they can hold them that long, is  
13 there something in the animal's gut that's necessary to  
14 germinate some of these mycorrhizal spores

15              The other question we asked is: Are  
16 there germination inhibitors in the spore coats, that  
17 the digestive juices of the animals leach out. We  
18 don't know. But these are some of the questions that  
19 we are only beginning to understand that need to be  
20 asked.

21              Anyway, at the end of six months of  
22 growing in the greenhouse we pulled these out and we do  
23 what we call reading the roots. Under a microscope we  
24 look at the roots, we test them for nitrogen-fixation  
25 and we found that all of the mycorrhizal fungi had

1       germinated, all three genre, there were high amounts of  
2       nitrogen-fixation in every test tube and they all had  
3       yeast and the yeast, in order to nourish the bacteria  
4       has to be alive.

5               So we tested this system with yeast from  
6       St. Lawrence Island, Alaska across the entire United  
7       States including the desert area with rabbits and hares  
8       to the east coast and found across the entire U.S.  
9       there is a range of animals that inoculate the soil  
10      with nitrogen-fixing bacteria.

11             So there is -- through their droppings  
12      there is a definite feedback loop, and it's these  
13      feedback loops that are so critical to maintaining the  
14      health of the system. We call them positive feedback  
15      loops, but if you start a negative cycle in a forest  
16      you still have a positive feedback loop that produces a  
17      negative result, and it's these feedback loops that we  
18      have to be very careful with because we are only  
19      beginning to understand how some of them might  
20      function.

21             Q.   No. 50.

22             A.   We clearcut and burn. Now, there are  
23      several things I would like you to be aware of on this  
24      slide. Remember I said this morning that we are making  
25      the wood -- or with the slide presentation, the large

1 woody material a finite resource. Take a look at this  
2 slope that was old growth. It was logged once, it came  
3 in with natural regeneration, and this is the logging  
4 of the first rotation.

5                   What nature gave us is not a rotation,  
6 that is a forest. The first rotation is the first  
7 harvest after the clearcutting. Look how little large  
8 wood is left. Look also how few large stumps are left,  
9 and look at how little of this wood is going along the  
10 contours. There is one big log going along the  
11 contour, these others are going up and down.

12                   When wood goes up and down the contour,  
13 it cannot store water because gravity pulls the water  
14 down to the lower end and it drips out the bottom. It  
15 can also not keep soil from ravelling downslope, like  
16 this one can, because there's nothing to hold the soil  
17 in place.

18                   Now, we have also found that small  
19 mammals using this as travel aids much more readily  
20 than they use logs up and down the slope. The surface  
21 of this -- this surface temperature in the summer would  
22 reach 160 degrees fahrenheit. The nitrogen-fixing  
23 bacterium that was in the deer mouse can withstand  
24 temperatures of 170 degrees or 80 degrees celsius, so  
25 if the deer mouse, which is not killed by these fires,

1 they are protected in their burrows, the fires are not  
2 hot enough to suck the oxygen out, when they come out,  
3 if they had fed on a mycorrhizal fruiting body within a  
4 month and if they've only nipped on it, if they have  
5 just taken a few bites they still have up to 25,000  
6 spores per pellet which means they can still inoculate  
7 the site.

8 When they come out and start moving  
9 around they are reinoculating these areas and the  
10 highest inoculum tends to be where the animals are most  
11 prevalent, and that is along the wood.

12 In the early days in the United States in  
13 the northwest we used to burn this type of material,  
14 pile it and burn it to get rid of rodent habitat  
15 because they ate seeds; today we are arranging the  
16 large woody material to manage for these rodent  
17 populations so they can begin to form the cyclic  
18 feedback loop of reinoculating the soil that we earlier  
19 took away.

20 Q. 51.

21 A. This is a Class 5 log. You will  
22 notice that it's completely buried and it's all heart  
23 wood and it has hemlock growing out of it. Embodied in  
24 this log, as long as it is in tact, the same as these  
25 two which are buried--

1 Q. No. 52.

2 A. --is roughly 50 to a hundred years of  
3 nutrient cycling that is still in place and free,  
4 provided we do not disrupt the continuity of that wood  
5 by dragging other logs over it or with caterpillars, or  
6 driving caterpillar tractors over it.

7 We are learning to stick more and more  
8 closely to defined skid trails if tractor logging is  
9 done to protect as much as we can of the already  
10 inherent nitrogen nutrient cycling that is in place.

11 Q. No. 53.

12 A. The fungi, the truffles attract the  
13 animals as they mature. This is an immature fruiting  
14 body and you will notice it's white, it has almost no  
15 odour.

16 As the truffles mature they get darker as  
17 the numbers of the maturing spores increase and they  
18 give off odours which are specific to the species, and  
19 we can detect the odours of many of them.

20 In Europe they train dogs and sows to  
21 sniff them out. In the early days they put muzzles on  
22 them--

23 Q. We're now looking at No. 57.

24 A. --and today they just harness the  
25 pigs like this, and they use sows not boars, the sow is

1 the female and the boar is the male.

2 These animals sniff the truffles out and  
3 they then dig them out and the famous Italian truffle  
4 today costs anywhere from \$600 to \$800 a pound because  
5 a change after World War II in forest management has  
6 that very important commercial crop on a drastic  
7 decline.

8 They use sows. I make a point of that,  
9 because the chemical odour, the feramone as we call it,  
10 that is given off by the truffle is identical to a boar  
11 that's ready to reproduce, that's physiologically ready  
12 to reproduce. So this association has been around for  
13 a very long time.

14 Q. 58.

15 A. In fact we are sure that when the  
16 continental drift took place since the mycorrhizal  
17 component goes back roughly 400-million years, that  
18 plants and animals, forests and their animal components  
19 evolved and moved, migrated together, because this is  
20 world wide and there are many similar species in Europe  
21 and the United States that share the same function,  
22 like red-backed voles in Europe, the red-backed voles  
23 in the United States, et cetera.

24 This is one the reasons that we are  
25 looking at this very carefully and trying to figure

1 out: How do forests migrate, and if we have to help  
2 them in management in the face of global warming, how  
3 do we do that?

4 In our part of the country the little  
5 chickaree, which your counterpart is the red squirrel,  
6 feeds on truffles.

7 Q. 59.

8 A. We find their pits and what they  
9 don't eat they tell us where to dig, we can glean for  
10 study.

11 Q. 60. This is No. 61.

12 A. We have found that organisms like  
13 shrews feed on the fungi.

14 Q. 62.

15 A. And the red-backed vole. This  
16 particular red-backed vole is confined to western  
17 Oregon and northwestern California.

18 On the coast 98 per cent of its diet are  
19 these fungal fruiting bodies that it's eating right  
20 here. When it moves inland to the Cascade Mountains,  
21 which are our north and south mountains, the diet drops  
22 to 85 per cent truffles and the rest is made up  
23 primarily with lichens.

24 If you go across the Columbia River into  
25 Washington, there's another species called the - this

1 is the western red-backed vole - the southern  
2 red-backed vole which goes from the Pacific Ocean to  
3 the Atlantic Ocean, goes across Canada, down the Rocky  
4 Mountains, down the Appalachians.

5 Its diet in the Olympic Peninsula is  
6 virtually a hundred per cent truffles. When you get to  
7 the Washington Cascades it's about 80 per cent, when  
8 you get to the Rockies, it's about 50 per cent because  
9 the Rockies are much more open, when you get to  
10 Carolina it's almost zero, but when you come up into  
11 the boreal forest again - and we looked at organisms  
12 from Ontario - it's virtually a hundred per cent.

13 We also had a paper which was just  
14 published this year in the Canadian Journal of Zoology  
15 looking at the tooth structure of these organisms and  
16 we found that as their diet shifted across North  
17 America the structure of their teeth shifted also. So  
18 they are adapted to the diet.

19 We found the same thing with the deer  
20 mouse across the country. The deer mouse fed very  
21 heavily on the mycorrhizal fungi in the Pacific  
22 northwestern forests, zero on the east coast, but when  
23 it comes back up through the boreal forest, in some  
24 areas it was virtually a hundred per cent again.

25 Now, this animal is dominant in the old

1 growth and there are studies in the northeastern part  
2 of the United States that show that clearcut logging,  
3 the same as in the west, eliminate this animal because  
4 in the conifer forests it is dependent very heavily on  
5 the mycorrhizal fungus for its diet. It in turn  
6 inoculates the soil.

7 We on the other hand have another small  
8 animal called a creeping vole which in our old growth  
9 forests can feed on these fungi belowground for  
10 centuries, for hundreds of generations. They are  
11 subordinate to the red-backed vole.

12 Now, most of the scientific literature  
13 states that the deer mouse is the common small mammal  
14 in the old growth forests. We found that it's not  
15 true, and it's not true because there are assumptions  
16 in the trapping of these animals that are inherently  
17 false.

18 One is that all of the animals like the  
19 same bait, they like it equally; well, deer mouse love  
20 peanut butter, but not every other rodent loves peanut  
21 butter. Deer mice are very exploratory, the red-backed  
22 voles that we worked with are not, they are more  
23 exploratory on the east coast. The animals do not use  
24 the surface of the ground equally.

25 So what we found was the red-backed vole

1 is the dominant animal but all the literature says the  
2 deer mouse is, and we demonstrated that because we do  
3 not use bait for red-backed voles, we trap them without  
4 bait by putting the traps in their runways, and you can  
5 use pitfall traps.

6 The deer mouse catch dropped 80 per cent  
7 and the red-back vole catch rose, so we know that the  
8 red-backed vole has been the dominant animal in the  
9 west.

10 During the 50s and 60s we asked the  
11 question: Why, when the old growth forest is removed,  
12 does this little animal absolutely explode in numbers  
13 and the red-backed vole die out of the clearcuts? Why  
14 is there a shift in the population?

15 But nobody looked at food habits until we  
16 started studying them a decade ago, and we found  
17 something very interesting that answered the question.  
18 This little animal can feed on the fungal fruiting  
19 bodies exclusively for generations, as does the red-  
20 backed vole, but the red-backed vole is the dominant  
21 animal and this one is subordinate.

22 As soon as the forest canopy is removed  
23 and the grasses and forbes come in, this little animal  
24 shifts its diet completely to grasses, for example, and  
25 its numbers explode and the red-backed vole dies out

1 within a year because when trees are cut and the roots  
2 die the fungus stops fruiting and the vole simply  
3 starves to death. As the forest comes back in, their  
4 population shifts again. So the dynamics of this are a  
5 continual cycle, there is nothing static, simple or  
6 easy about its.

7 Q. No. 64.

8 A. Chipmunks and deer mice are very  
9 important inoculum because they go to the established  
10 forest where they feed on the spores and their fruiting  
11 bodies and then they go out and visit the clearcuts and  
12 they inoculate the soil as they go.

13 I don't know about your clearcuts, but  
14 ours, we very often find that the trees do their best  
15 right around the edge and conventional wisdom has said  
16 that's the distance that the seeds fall, that is where  
17 the wind blows them, and that is shade.

18 That may all be part of it, but I went  
19 back to the animal damaged data that was collected at  
20 the cost of millions of dollars and reinterpreted it  
21 and I asked the question: If these little animals have  
22 in their droppings the ability to inoculate soil, what  
23 is their home range, how far out into clearcuts do they  
24 go?

25 And so reinterpreting the damaged data we

1       then looked at soil and found out that the ring that  
2       does the best around the edge of established trees is  
3       the distance these little mammals visit into the  
4       clearcut from the edge.

5               So all we did was reinterpret the data  
6       that was looked at very narrowly and we looked at it  
7       broader and found that these little animals do in fact  
8       go out this distance, they do eat some seeds, they also  
9       inoculate the soil.

10              There was a study done on the east coast  
11       which to me was seminal. When we first came out with  
12       our experiment nobody seemed to pay much attention  
13       except for one pair of researchers dealing with trying  
14       to reclaim mine spoils, and they were doing the same  
15       thing, they were trapping all the rodents, poisoning  
16       them because they saw them eating vegetation they were  
17       trying to get established.

18              After they read the paper that we had  
19       written, they did some experiments and found where they  
20       excluded the animal, so they couldn't get in, the  
21       vegetation died; where the animals and vegetation were  
22       together, it survived because they found those animals  
23       were also moving around the mycorrhizal inoculant that  
24       the mining spoils needed in order to be able to  
25       survive.

1                   There is an animal that you have in  
2       Canada called a heather vole, we have it in the States  
3       too, and at high elevation they are the little  
4       organisms on mudflows from glaciers and on the moving  
5       creeping timber line allow the trees to become  
6       established in meadows. They feed in the winter on the  
7       mycorrhizal component and they have tremendous toilets,  
8       where they go potty just in one area, and that  
9       inoculates the soil to such an extent that the timber  
10      line can creep up to those areas as the seeds get  
11      there. And we've documented this on mudflows on Mount  
12      Ranier. Those small organisms live at the edge of the  
13      habitats, they are very docile animals, they do not  
14      stand competition, but they are responsible in many  
15      areas for the creeping timber line and the  
16      recolonization of severely disturbed sites.

17                   Q. No. 65.

18                   A. The pica also is very important in  
19      high elevation around talus or rock slides. We have  
20      another organism called a mantled brown squirrel--

21                   Q. 66.

22                   A. --which feeds on the truffles in the  
23      pine area, the ponderosa and large-pole pine and is  
24      very instrumental in the pine area.

25                   Q. 67.

1                   A. And the northern flying squirrel.  
2       The northern flying squirrel is one of our more  
3       important fungus feeders. I will use this as an  
4       example of a positive feedback loop and then I will go  
5       on.

6                   You have the northern flying squirrel  
7       here and studies have been done at Fairbanks Alaska  
8       where the flying squirrel is probably the critical  
9       fungus feeder in that part of the country. It lives in  
10      mistletoe brooms, in the big witches' broom on the  
11      trees that are infected with mistletoe. It feeds on  
12      the fungi and the fungi grow only a certain distance  
13      out from the dead wood. It's much more confined to the  
14      wood than it is further south.

15                  Now, the flying squirrel nests in the  
16      tree tops and it reproduces in the tree tops, but it  
17      comes down, it glides down at night - they can't fly,  
18      they can only glide on membranes - they come down to  
19      the forest floor at night and they sniff out the  
20      fruiting bodies of the truffles. They eat the truffle.  
21      If in sniffing out a fruiting body and disturbing the  
22      soil they uncover a root tip which has not been  
23      inoculated and they leave a little pooparoony there,  
24      the yeast can stimulate the germination of the  
25      mycorrhizal spores, the nitrogen-fixing bacteria kicks

1 in and produced nitrogen, this whole little thing then  
2 inoculates the root tip and it might be of the  
3 squirrel's own tree.

4 So in this sense the squirrel is keeping  
5 the forest that it depends on healthy in a positive  
6 feedback loop and rodents are doing this 24 hours a  
7 day; above ground from the tree tops when they  
8 defecate, belowground and on the surface.

9 Now, let's assume that the root tip that  
10 it has dug out is already inoculated, it has this  
11 mantle around it, and it leaves a calling card but that  
12 calling card is the same species of fungus that that  
13 root tip already is inoculated with, then the  
14 non-reproductive part of the fungus called the thallus,  
15 they fuse, and that is one of the ways genetic material  
16 is exchanged throughout the forest.

17 And this is important because the rodents  
18 move all around the forest, they have what we call a  
19 home range, an area of normal habitat use. There may  
20 be -- some of them -- some of ours, I'm used to acres,  
21 but an acre, two acres, a hectare or more, and they  
22 pick up the fungus here and they drop it over there  
23 with their droppings, so they are moving the genetic  
24 material around the forest. That is one of the ways  
25 that it gets moved.

1                   We also couldn't figure out for a long  
2 time - I studied bob cat and cougar - mountain lion  
3 food habits, I found flying squirrels in their  
4 droppings and coyotes. We finally figures out they're  
5 vulnerable when they're on the ground feeding.

6                   The other thing we've looked at was that  
7 the data from some of the wildlife surveys showed the  
8 flying squirrel was very closely tied to large amounts  
9 of large dead wood. So when we put the pieces together  
10 and we looked at how the fungus fruits, we then looked  
11 at the spotted owl which has caused -- that issue has  
12 caused all the fervor in the northwest, a very  
13 interesting feedback loop showed up.

14                  The spotted owl lives in old growth  
15 trees, our old growth forests are high in amounts of  
16 dead wood, the dead wood is where the fungus fruits  
17 most prolifically and that's where the moisture is.

18                  The flying squirrel lives in the tree  
19 tops, comes down and feeds on the fungus which is  
20 dependent on the wood and the flying squirrel is the  
21 main prey of the spotted owl.

22                  So if we remove, as industry has  
23 suggested, if we allow them to highgrade the forest  
24 floor, which is disturbing the cycle, the feedback loop  
25 of the old growth, we remove the wood that has an

1 impact on the fungus, has an impact on the squirrel, we  
2 lose the owl. And this shows that then the whole  
3 system begins to reorganize but it will be different,  
4 we have lost the integrity of the old growth.

5 So if we are to set old growth aside as a  
6 system for future reference for its potential to learn  
7 from, we must maintain its integrity because we do not  
8 know, with a very simple act of -- salvage is the most  
9 dangerous thing we do across the board in my opinion,  
10 because we say that wood out there has no value unless  
11 it's at the mill and that's what industry has asked  
12 over the years: Can't we just salvage this dead wood  
13 in the old growth? But then you lose the integrity of  
14 the system because now you start a negative positive  
15 feedback loop, one that has negative impacts, and those  
16 are the things that we need to become cognizant of.

17 Q. No. 68.

18 A. Deer - this happens to be a mule  
19 deer - elk and bear move the mycorrhizal fungus vast  
20 miles. One elk can travel up to 50 miles a day easily.

21 I asked a friend of mine who was studying  
22 elk to collect droppings for me on a monthly basis, and  
23 we found that elk and deer feed on the mycorrhizae  
24 whenever and wherever they are available.

25 Now, a couple of things about the flying

1 squirrel before I bring this part to a close. The  
2 flying squirrel in northern Oregon feeds on the  
3 truffles spring, summer and fall but they are  
4 unavailable in the winter, the same is true in Alaska,  
5 so the squirrels shift their diets to lichens in the  
6 tree top and these are old growth trees.

7 The squirrels do far better in an old  
8 growth system than they do in a young growth system,  
9 that is their preferred habitat, that doesn't mean they  
10 don't live in second growth forests or young growth  
11 forests.

12 In southern Oregon -- southwestern Oregon  
13 the squirrels feed on the fungus year round because it  
14 is not unavailable, it is available all the time.

15 So again I would caution about making  
16 blanket statements about any areas, other than saying  
17 the principles are a common denominator, but there is  
18 variability throughout the system. We simply cannot  
19 make blanket statements. These are what we call  
20 symbiotic pills, these are the droppings of the flying  
21 squirrel.

22 Q. This is No. 69.

23 A. And it's these little components that  
24 can inoculate seedlings. Consider that if a deer mouse  
25 gives off 66 pellets a night with the total compliment

1 that's necessary, consider also that there is enough  
2 nutrients in a pellet to the maintain the health of the  
3 spores in the bacteria, and consider also that these  
4 pellets contain something, a kind of anti-freeze - we  
5 don't know what it is - that prevents the  
6 nitrogen-fixing bacteria from rupturing during  
7 freezing.

8 Microbiologists dried --they freeze-dry  
9 bacteria to save them for long periods of time because  
10 if they freeze them wet, that is normally, when they  
11 thawed the,membrane ruptures and bacteria is killed.

12 Inside the droppings we found is  
13 something that prevents them from freezing, so these  
14 can be over wintered and inoculate the soil in the  
15 spring.

16 So when you have considered all of this  
17 and that this is constantly being put into the system  
18 and then you have the deer mouse, which if you have  
19 five deer mice at 66 pellets a night, that's roughly  
20 1,000 pellets in five nights that have enough inoculum  
21 that if one was dropped by a root tip of -- it's 990  
22 some trees, you could inoculate those root tips with  
23 life.

24 When you have the rodents performing this  
25 function throughout the forest over and over and over

1 and you simplified the habitat above ground which  
2 automatically simplifies it and the processes  
3 belowground, we can have a dramatic impact on how these  
4 forests function.

5 Because we must remember, half of the  
6 forest is belowground but we only manage what we see  
7 above ground. We cannot have an impact above the  
8 surface without having a simultaneous and similar  
9 impact in magnitude belowground.

10 Q. Mr. Maser, perhaps if we could just  
11 pause there.

12 MR. LINDGREN: Madam Chair, we have  
13 approximately eight slides left. We could finish them  
14 now or put it over until tomorrow morning.

15 MADAM CHAIR: Why don't we stop now and  
16 we will pick it up in the morning, Mr. Maser.

17 THE WITNESS: Okay. It's my pleasure.

18 MADAM CHAIR: Thank you.

19 MR. LINDGREN: And, Madam Chair, I can  
20 advise that if we are not finished by noon, we will be  
21 finished shortly thereafter, so I would suggest that  
22 Mr. Hanna be contacted and be advised that he is likely  
23 to be called tomorrow afternoon.

24 MADAM CHAIR: Thank you, Mr. Lindgren.

25 And we will be back tomorrow morning at

1 nine o'clock.

2 MR. LINDGREN: Thank you.

3 MADAM CHAIR: Thank you.

4 ---Whereupon the hearing adjourned at 4:00 p.m., to be  
5 reconvened on Tuesday, January 29th, 1991 commencing  
6 at 9:00 a.m.
